Example

A company must complete 3 jobs on 4 machines, requiring the following processing times:

	Machine			
Job	1	2	3	4
1	20		25	30
2	15	20		18
3		35	28	

45

A job cannot be processed on machine j unless for all i<j, the job has completed processing on machine i.

The "flow time" of a job is the difference between the completion time and the time it begins its first stage of processing.

The company wishes to minimize the average flow time of the three jobs.

Model

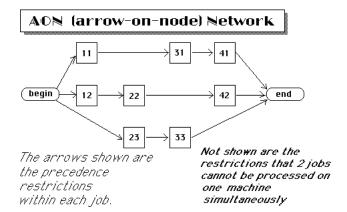

This is a project scheduling problem, with some added restrictions and a different objective.

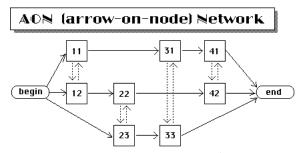

There are 8 tasks to be performed (processing of jobs on machines) with precedence restrictions.

Label the tasks

 $ij \approx processing of job j on machine i$

For example, tasks 11 and 12 cannot be in progress simultaneously; one of them must precede the other. *But which?*

Exactly one arrow of each pair (with dotted lines) is to be selected!

Decision Variables

We will define binary variables to represent this decision:

$$X_{ij} = \begin{cases} 1 & \text{if job j is the first to be processed} \\ & \text{on machine i} \\ 0 & \text{otherwise} \end{cases}$$

Decision Variables

In addition to the binary variables, we need to define variables as in the LP formulation of the critical path problem:

 t_{ii} = starting time of task ij

Objective

Flow time of a job is the difference between the completion time of the last task of the job, and the start time of the first task of the job. For example, for job #1,

$$t_{41}$$
+ 30 = completion time of task 41
 t_{11} = start time of task 11
 $(t_{41}$ + 30) - t_{11} = Flow time for job #1

Objective

Minimize average flow time:

Minimize
$$\frac{[t_{41}-t_{11}+30]+[t_{42}-t_{12}+18]+[t_{33}-t_{23}+28]}{3}$$

This is equivalent to minimizing the sum of the flow times, which (omitting constants) is

Minimize
$$t_{41}$$
- t_{11} + t_{42} - t_{12} + t_{33} - t_{23}

Constraints

One precedence between jobs on each machine must be selected:

e.q.,

$$X_{11} + X_{12} = 1$$
, i.e., either job 1 or job 2 must be first to be processed on machine 1

Constraints

There are the within-job precedence constraints: for example,

$$t_{13} \ge t_{11} + 20$$

i.e., start time of task 13 must be later (or equal) to completion time of task 11

Constraints

We must also include the within-machine precedence constraints:

for example, (If job 1 is NOT first on machine 1,
$$t_{11} \geq t_{12} + 15 - M \times_{11}$$
 then it must start AFTER job 2 is completed.)
$$t_{12} \geq t_{11} + 20 - M \times_{12}$$

where "M" is a sufficiently big number.

		Daily
Truck	Capacity	operating
#	(gal.)	cost(\$)
1	400	45
2	500	50
3	600	55
4	1100	60

Grocery #	Daily demand (gal.)
1	100
2	200
3	300
4	500
5	800

Example

Four trucks are available to deliver milk to 5 groceries. Capacities & daily operating costs vary among the trucks. Demand of each grocery may be supplied by only one truck, but a truck may deliver to more than one grocery.

Formulate an ILP to minimize the daily cost of meeting the demands of the 5 groceries.

(data on next card)

Decision Variables

Define

$$Y_i = \begin{cases} 1 & \text{if truck i is used} \\ 0 & \text{otherwise} \end{cases}$$

$$X_{ij} = \begin{cases} 1 & \text{if truck i delivers to grocery j} \\ 0 & \text{otherwise} \end{cases}$$

Objective |

Minimize the daily operating costs

Minimize
$$\sum_{i=1}^{4} C_i Y_i$$

where C_i = daily operating cost of truck i

i.e., Minimize
$$45Y_1 + 50Y_2 + 55Y_3 + 60Y_4$$

Constraints

Each grocery must be on a delivery route:

$$\sum_{i=1}^{4} X_{ij} = 1$$
, for j=1,...5

e.g.,
$$X_{11} + X_{21} + X_{31} + X_{41} = 1$$

Constraints

The deliveries made by a truck i should not exceed its capacity K_i :

$$\sum_{i=1}^{5} D_{i}X_{ij} \leq K_{i}, \text{ for } i=1,...4$$

where D_j = demand of grocery j e.g., for truck #1:

$$100X_{11} + 200X_{12} + 300X_{13} + 500X_{14} + 800X_{15} \le 400$$

Constraints

We need constraints which force X_{ij} =0 if Y_i =0, i.e., if truck i is not used, it cannot deliver to a grocery.

One way to do this is to include constraints

$$X_{ij} \le Y_i$$
 for all 20 combinations of i & j

Constraints

Another way to force X_{ij} =0 if Y_i =0 is to modify the earlier truck capacity constraints, adding a factor Y to the RHS:

$$\sum_{j=1}^{5} \, \mathsf{D}_j \mathsf{X}_{ij} \leq \mathsf{K}_i \mathsf{Y}_i, \, \mathsf{for} \, \, i \! = \! 1, \ldots 4$$

e.g.,

$$100X_{11} + 200X_{12} + 300X_{13} + 500X_{14} + 800X_{15} \le 400Y_{i}$$

Regis	Registered Voters (thousands)		
City	Republicans	Democrats	
1 2	80 60	30 40	
23456	40 20	40 20	
5	40	110	
7	40 70	60 20	
8 50 9 70		40 50	
10	Źŏ	6ŏ	

Gov. Blue is a Democrat. Formulate an ILP to maximize the number of Democratic congressmen, assuming voters vote a straight party ticket.

Example

Governor Blue of the State of Berry is attempting to get the state legislature to "gerrymander" Berry's 5 congressional districts.

The state consists of 10 cities. To form districts, cities must be grouped according to the following restrictions:

- All voters in a city must be in the same district.
- Each district must contain between 150,000 and 250,000 voters.

Decision Variables

$$X_{ij} \ = \ \begin{cases} 1 & \text{if district i includes city j} \\ 0 & \text{otherwise} \end{cases}$$

$$Y_i = \begin{cases} 1 & \text{if district i has a Democratic majority} \\ 0 & \text{otherwise} \end{cases}$$

(assume no independent voters!)

Model

Objective

Maximize the number of districts with Democratic majorities:

Maximize
$$Y_1 + Y_2 + Y_3 + Y_4 + Y_5$$

Constraints

Every city must be assigned to a district:

$$\sum_{i=1}^{n} X_{ij} = 1 \quad \forall \ j=1,...10$$

For example, in the case of city 1 (j=1):

$$X_{11}+X_{21}+X_{31}+X_{41}+X_{51}=1$$

Constraints

The population of a district must be in the range from 150 thousand to 250 thousand:

$$150 \le \sum_{j=1}^{10} P_j X_{ij} \le 250 \quad \forall i=1,2,3,4,5$$

where P_i = population of city j (in thousands)

Constraints

 Y_i = 1 only if there is a Democratic majority in

district i, i.e., only if
$$\sum_{\substack{j=1\\10\\j=1}}^{10} D_j X_{ij} \ge \frac{1}{2}$$

$$\Longrightarrow \sum_{j=1}^{10} D_j X_{ij} \ge \frac{1}{2} \sum_{j=1}^{10} P_j X_{ij} \Longrightarrow \sum_{j=1}^{10} (D_j - \frac{1}{2}P_j) X_{ij} \ge 0$$

Constraints

$$\begin{array}{lll} \text{We wish to} & \displaystyle \int\limits_{ip=1}^{10} \left(D_j - \frac{1}{2} P_j\right) \, X_{ij} \geq \, 0 & \text{if } Y_i = 1 \\ & \displaystyle \sum\limits_{j=1}^{10} \left(D_j - \frac{1}{2} P_j\right) \, X_{ij} \geq - \infty & \text{if } Y_i = 0 \end{array}$$

i.e.,
$$\sum_{j=1}^{10} (D_j - \frac{1}{2}P_j) X_{ij} \ge -M(1-Y_i) \quad \text{for "M"}$$
 sufficiently

Note that there is lacking in this model any consideration of the geographical location of the cities, so that the districts which are formed may not be "nicely" shaped, and in fact may not even be connected!

Actual computer models for this problem should contain constraints to ensure that the districts are connected and "compact", i.e., the ratio of length to width should be "close" to 1.

SUBJECT TO X11 + X12 + X13 + X14 + X15 = X21 + X22 + X23 + X24 + X25 = X31 + X32 + X33 + X34 + X35 = X41 + X42 + X43 + X44 + X45 = X51 + X52 + X53 + X54 + X55 = X61 + X62 + X63 + X64 + X65 = X71 + X72 + X73 + X74 + X75 = X81 + X82 + X83 + X84 + X85 = X91 + X92 + X93 + X94 + X95 =+ 90 X83 + 120 X93 + 130 X103 - S3 = 150 15) 110 X14 + 100 X24 + 80 X34 + 40 X44 + 150 X54 + 100 X64 + 90 X74

Optimal Solution

	Fuel	Demand	Cost per	Max allowed
	type	(gal.)	gal. short	shortage
ſ	super	2900	\$10	500
	regular	4000	\$8	500
	unleaded	4900	\$6	500

Formulate an ILP model to find the loading of the truck which minimizes shortage costs.

Model

Objective

Example

A Sunco oil delivery truck contains 5 compartments, holding up to 2700, 2800,1100, 1800, and 3400 gallons of fuel, respectively.

The company must deliver 3 types of fuel (super, regular, and unleaded) to a customer. Each compartment can carry only one type of fuel.
