

**A Brief Intro
to
QUEUEING
THEORY**

Kendall's Notation

- M: Memoryless (Markovian)
- E_k : Erlang-k
- D: Deterministic
- GI: General Interarrival times (but i.i.d.)
- G: General service times (but i.i.d.)

The "Memoryless" arrival process indicates a Poisson arrival process, in which the interarrival times have an *exponential* distribution.

Likewise, the "Memoryless" service process indicates that the service times have an *exponential* distribution.

©D.L.Bricker, U. of IA, 1999

LITTLE's Queueing Formula

$$L = \lambda W$$

average number in the queueing system *average arrival rate* *average time in system per customer*

 applies to *any* queueing system having a steady state distribution

©D.L.Bricker, U. of IA, 1999

LITTLE's Queueing Formula

$$L = \lambda W$$

Intuitive argument:

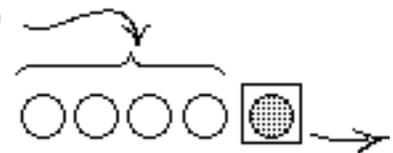

Suppose that you join a queue and spend W minutes before you have been served and leave.

During those W minutes, customers have been arriving and joining the queue behind you at the average rate of λ per minute. Thus, when you are ready to leave, you should expect to see λW customers remaining in the system behind you.

you enter queue

entered queue behind you

©D.L.Bricker, U. of IA, 1999

time W

Most theoretical results have been obtained for the case in which both inter-arrival times and service times are *memoryless* (have *exponential* dist'n):

- ☞ M/M/1
- ☞ M/M/c (c > 1)
- ☞ M/M/1/N
- ☞ M/M/1/N/N

A case in which service time is not memoryless:

- ☞ M/G/1

☞ Exercises

M/M/1

Interarrival times and service times both have exponential distributions, with parameters λ & μ , respectively.

That is, the "customers" arrive at the rate of λ per unit time, and are served at the rate μ per unit of time.

It is assumed that the queue has infinite capacity, and that $\mu > \lambda$ (so that the queue length does not tend to increase indefinitely.)

In this case, it is possible to derive the probability distribution of the number of customers in the queueing system. ↩

©D.L.Bricker, U. of IA, 1999

M/M/1

$\pi = (\pi_0, \pi_1, \pi_2, \dots)$ denotes the "steady-state" distribution of the number of customers in this M/M/1 queueing system, i.e., 1+number in queue.

Equivalently, π_i is the probability (in steady state) that an arriving customer will find i customers already in the queueing system.

$$\pi_i = \left(1 - \frac{\lambda}{\mu}\right) \left(\frac{\lambda}{\mu}\right)^i$$

©D.L.Bricker, U. of IA, 1999

M/M/1

Using this probability distribution, we can then derive the average number of customers in the system:

$$L = \sum_{i=0}^{\infty} i \pi_i = \sum_{i=0}^{\infty} i \left(1 - \frac{\lambda}{\mu}\right) \left(\frac{\lambda}{\mu}\right)^i$$

$$\Rightarrow L = \frac{\frac{\lambda}{\mu}}{1 - \frac{\lambda}{\mu}} = \frac{\rho}{1 - \rho}$$

where

$$\rho = \frac{\lambda}{\mu} < 1$$

©D.L.Bricker, U. of IA, 1999

M/M/1

For the M/M/1 queueing system, Little's formula implies that

$$W = \frac{L}{\lambda} = \frac{\rho}{\lambda(1 - \rho)}$$

$$\Rightarrow W = \frac{1}{\mu - \lambda}$$

©D.L.Bricker, U. of IA, 1999

M/M/1

For the M/M/1 queueing system, then

$$W_q = W - \frac{1}{\mu} \implies W_q = \frac{\lambda}{\mu(\mu - \lambda)}$$

$$L_q = \lambda W_q \implies L_q = \frac{\lambda^2}{\mu(\mu - \lambda)}$$

©D.L.Bricker, U. of IA, 1999

Example

An average of 24 trucks per 8-hour day arrive to be unloaded &/or loaded, which requires an average of 15 minutes.

The loading dock can handle only a single truck at a time.

Assume that the arrival process is Poisson, and that the service times have exponential distribution.

This loading dock is modeled as an M/M/1 queue.

©D.L.Bricker, U. of IA, 1999

M/M/1 λ = arrival rate = 3/hour μ = service rate = 4/hour*Utilization
of the server*

$$\rho = \frac{\lambda}{\mu} = 0.75$$

*Average number of
trucks in system*

$$L = \frac{\rho}{1 - \rho} = \frac{0.75}{1 - 0.75} = 3$$

*Average time in
system per truck*

$$W = \frac{L}{\lambda} = \frac{3}{3/\text{hr}} = 1 \text{ hr.}$$

Steady-state Behavior

©D.L.Bricker, U. of IA, 1999

M/M/1 λ = arrival rate = 3/hour μ = service rate = 4/hour*Average time in
the queue*

$$W_q = W - \frac{1}{\mu} = 1 \text{ hr.} - \frac{1}{4/\text{hr}} \\ = 0.75 \text{ hr.}$$

*Average length
of the queue*

$$L_q = \lambda W_q = (3/\text{hr})(0.75\text{hr}) \\ = 2.25$$

©D.L.Bricker, U. of IA, 1999

M/M/c

- *Arrival & Service processes are Memoryless, i.e., interarrival times have Exponential distribution with mean $1/\lambda$ service times have Exponential distribution with mean $1/\mu$*
- *Number of servers is c*
- *Capacity of queueing system is infinite*

©D.L.Bricker, U. of IA, 1999

M/M/c

If the arrival rate λ is less than the combined rate $c\mu$ at which the servers can work, then the system will have a *steadystate* distribution, given by:

$$\pi_0 = \frac{1}{\sum_{n=0}^{c-1} \frac{(c\rho)^n}{n!} + \frac{(c\rho)^c}{c!} \frac{1}{1-\rho}}$$

$$\pi_j = \frac{(c\rho)^j}{j!} \pi_0, \quad j=1,2,\dots,c$$

$$\pi_j = \frac{(c\rho)^j}{c!c^{j-c}} \pi_0, \quad j=c,c+1,\dots$$

where $\rho = \frac{\lambda}{c\mu} < 1$

©D.L.Bricker, U. of IA, 1999

Probability that all servers are busy:

$$\sum_{j \geq c} \pi_j = \frac{(c\rho)^c}{c!(1-\rho)} \pi_0 \quad \text{where } \rho = \frac{\lambda}{c\mu} < 1$$

This, then, is the probability that an arriving customer will be required to wait for service!

©D.L.Bricker, U. of IA, 1999

M/M/c

Average Length of Queue

(not including those being served)

$$L_q = \sum_{j=0}^{\infty} j \pi_{c+j} = \sum_{j=0}^{\infty} j \pi_0 \frac{(c\rho)^{c+j}}{c! c^j} = \pi_0 \frac{(c\rho)^c}{c!} \sum_{j=0}^{\infty} j \rho^j$$

$$\rho = \frac{\lambda}{c\mu}$$

©D.L.Bricker, U. of IA, 1999

M/M/c

Average Length of Queue

(not including those being served)

$$L_q = \frac{\rho (c\rho)^c}{c!} \pi_0 \left(\frac{1}{1-\rho}\right)^2$$

Once L_q is computed, then we can compute (using Little's formula)

$$W_q = \frac{L_q}{\lambda}, \quad W = W_q + \frac{1}{\mu}, \quad \& \quad L = \lambda W$$

©D.L.Bricker, U. of IA, 1999

Example: Pooled vs. Separate Servers

Compare two queueing systems:

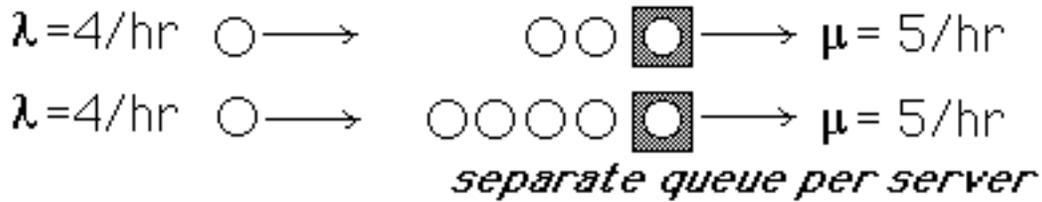

separate queue per server

pooled servers

©D.L.Bricker, U. of IA, 1999

two M/M/1 queues

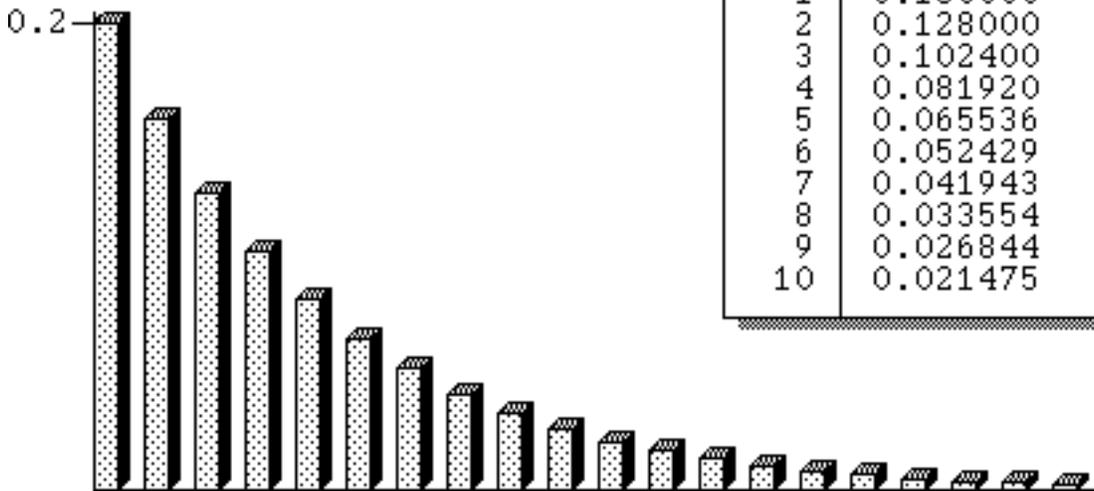

Average waiting time: $W_q = \frac{\lambda}{\mu(\mu - \lambda)}$

$W_q = \frac{4/\text{hr}}{(5/\text{hr})(5-4)/\text{hr}} = 0.8 \text{ hr}$
 (48 minutes)

©D.L.Bricker, U. of IA, 1999

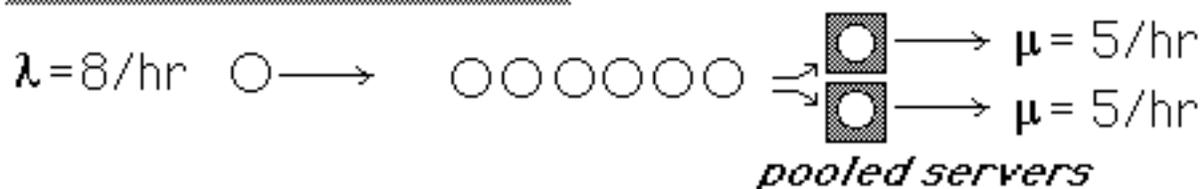

Steady-State Distribution

i	Pi	CDF

single M/M/2 queue

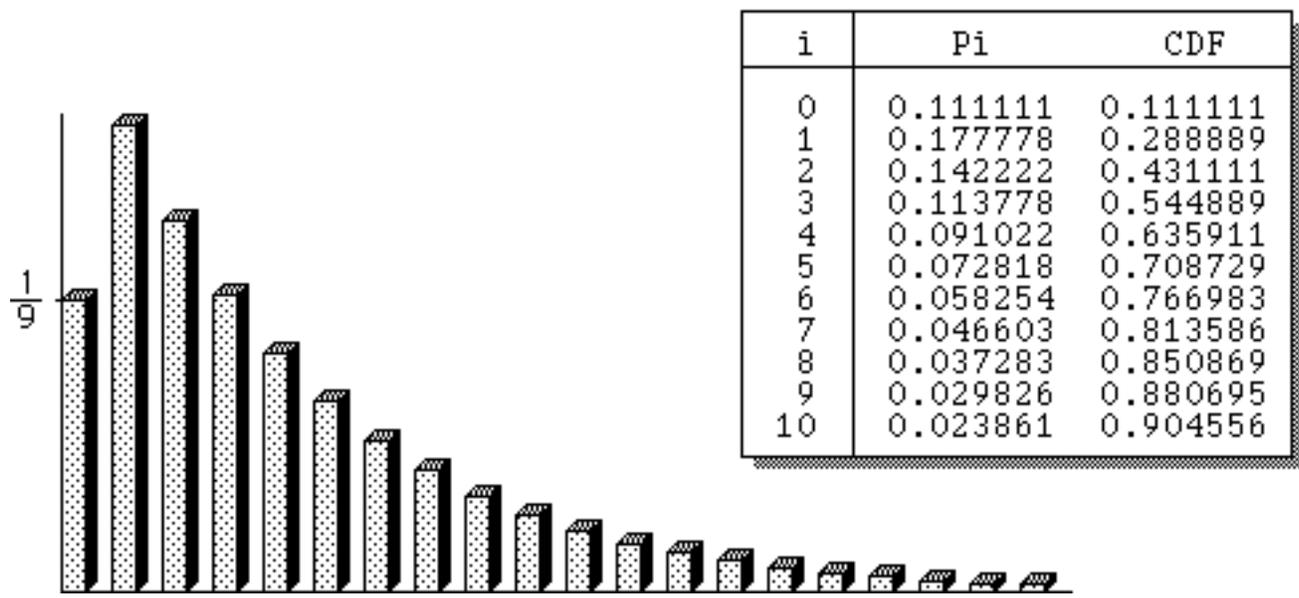

Rather than maintaining a separate queue for each server, customers enter a common queue.

$$\rho = \frac{\lambda}{2\mu} = \frac{8/\text{hr}}{2 \times 5/\text{hr}} = 0.8 < 1 \quad \text{which implies that a steady state exists!}$$

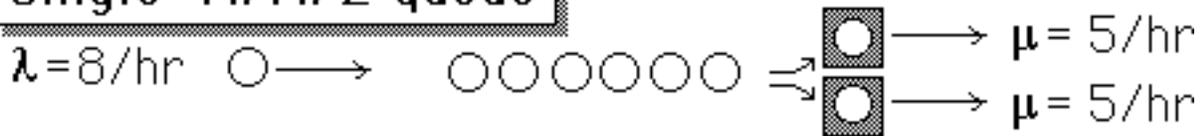

©D.L.Bricker, U. of IA, 1999

Steady-State Distribution

©D.L.Bricker, U. of IA, 1999

single M/M/2 queue

$$L_q = \frac{\rho}{1 - \rho} P\{\text{both servers busy}\}$$

$$= \frac{0.8}{0.2} (0.71111111) = 2.844444444$$

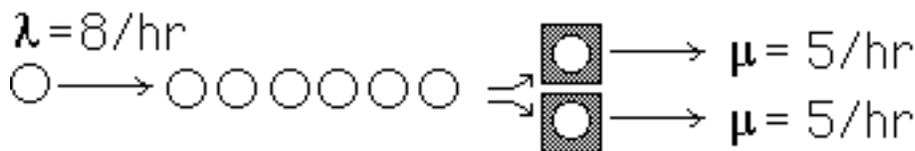

$$W_q = \frac{L_q}{\lambda} = 0.35156 \text{ hr.} = 21.1 \text{ minutes}$$

©D.L.Bricker, U. of IA, 1999

separate queue per server

$$W_q = 0.8 \text{ hr.} = 48 \text{ min.}$$

pooled servers

$$W_q = 0.352 \text{ hr.} = 21.1 \text{ min.}$$

By pooling the servers, the average waiting time per customer is reduced by approximately 56%

©D.L.Bricker, U. of IA, 1999

M/M/1/N

- *Arrival & Service processes are **Memoryless**, i.e., interarrival times have Exponential distribution with mean $1/\lambda$ service times have Exponential distribution with mean $1/\mu$*
- *Single server*
- ***Capacity** of queueing system is **finite**: N (including customer currently being served)*
- *Arriving customers **balk** when queue is full.*

©D.L.Bricker, U. of IA, 1999

M/M/1/N***Steadystate Distribution***

$$\pi_0 = \frac{1 - \rho}{1 - \rho^{N+1}}$$

$$\pi_j = \rho^j \pi_0 = \rho^j \left(\frac{1 - \rho}{1 - \rho^{N+1}} \right)$$

where $\rho = \frac{\lambda}{\mu} \neq 1$

Note that ρ is not restricted to be less than 1 for steady state to exist!

©D.L.Bricker, U. of IA, 1999

Average Number of Customers in System

$$L = \sum_{j=0}^N j \pi_j$$

$$L = \frac{\rho [1 - (N+1)\rho^N + N\rho^{N+1}]}{(1 - \rho^{N+1})(1 - \rho)}$$

where $\rho = \frac{\lambda}{\mu} \neq 1$

©D.L.Bricker, U. of IA, 1999

M/M/1/N

Special Case: $\lambda = \mu$, i.e., $\rho = \frac{\lambda}{\mu} = 1$

Arrival rate = Service rate

$$\pi_j = \frac{1}{N+1}$$

$$L = \frac{N}{2}$$

All states are equally likely!

System is, on average, half-full!

©D.L.Bricker, U. of IA, 1999

Average Time in System per Customer

Little's Formula: $L = \lambda W$
↑
average arrival rate

$$\lambda = \sum_{j=0}^{N-1} \lambda \pi_j = \lambda \sum_{j=0}^{N-1} \pi_j = \lambda (1 - \pi_N)$$

since arrival rate is zero when there are N in system

$$W = \frac{L}{\lambda} = \frac{L}{\lambda(1 - \pi_N)}$$

©D.L.Bricker, U. of IA, 1999

M/M/1/N/N

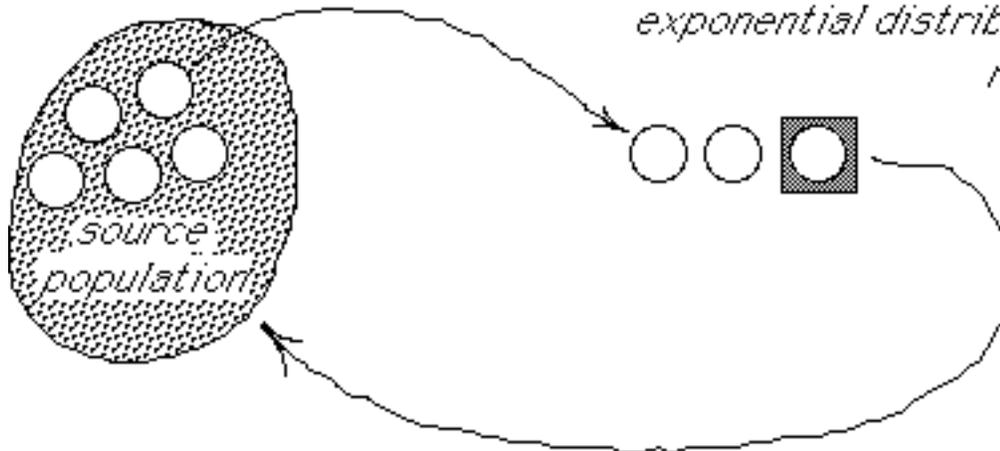

- *Single server*
- *Finite Source Population of size N*
- *Arrival & Service processes are **Memoryless**, i.e., service times have Exponential distribution with mean $1/\mu$*
- *A departing customer returns to the queue after a time having an Exponential distribution with mean $1/\lambda$*

©D.L.Bricker, U. of IA, 1999

M/M/1/N/N

Each customer, after being served, returns to the source population for a length of time having exponential distribution with mean $1/\lambda$

©D.L.Bricker, U. of IA, 1999

M/M/1/N/N

Steadystate Distribution

$$\pi_0 = \frac{1}{\sum_{j=0}^N \frac{N!}{(N-j)!} \rho^j}$$

$$\pi_j = \frac{N!}{(N-j)!} \rho^j \pi_0$$

First calculate the probability π_0 that the server is idle.

Other probabilities are then multiples of π_0

where $\rho = \frac{\lambda}{\mu}$

©D.L.Bricker, U. of IA, 1999

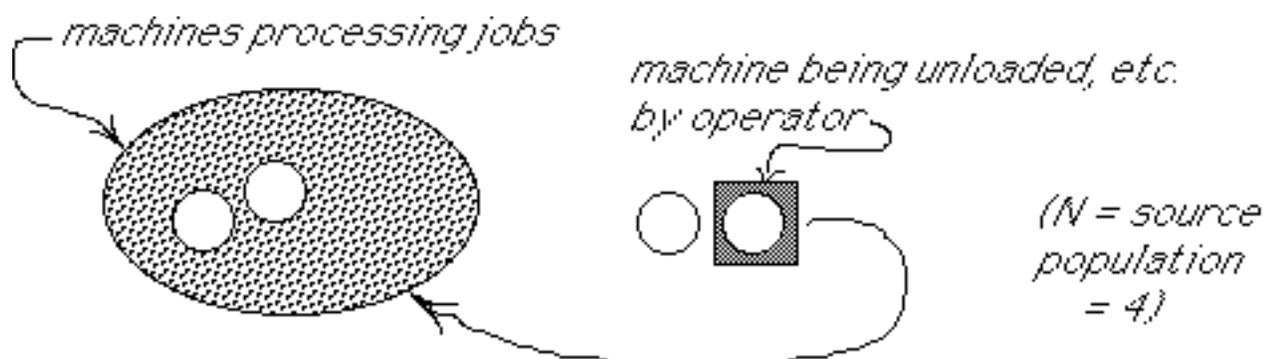

Example

An operator can be assigned to service (load, unload, adjust, etc.) several automatic machines in a factory

- Running time of each machine before it must be serviced has exponential distribution, with mean 120 minutes.
- Service time has an exponential distribution with mean 12 minutes.

To achieve a desired utilization of $\geq 87.5\%$ for the machines, how many machines should be assigned to the operator?

©D.L.Bricker, U. of IA, 1999

This can be modeled as a M/M/1 queueing system with finite source population.

Machine operator = server

Machines = customers

$$\mu = 5/\text{hour}$$

$$\lambda = 0.5/\text{hour}$$

©D.L.Bricker, U. of IA, 1999

$$\frac{1}{\pi_0} = \sum_{j=0}^3 \frac{3!}{(3-j)!} (0.1)^j$$

Steadystate
Distribution

$$= 1 + 0.3 + 0.06 + 0.006$$

$$= 1.366$$

$$\pi_0 = \frac{1}{1.366} = 0.732965$$

*i.e., operator will
be idle about 73%
of the time!*

$$\pi_1 = 0.3 \pi_0 = 0.2196$$

$$\pi_2 = 0.06 \pi_0 = 0.0439$$

$$\pi_3 = 0.006 \pi_0 = 0.0044$$

©D.L.Bricker, U. of IA, 1999

$$\pi_0 = 0.732965$$

$$\pi_1 = 0.2196$$

$$\pi_2 = 0.0439$$

$$\pi_3 = 0.0044$$

*If 0 machines are in system, then
3 are busy processing jobs;*

*if 1 machine is in system, then 2
are busy processing jobs, etc.*

Average utilization of the machines will be

$$\frac{3 \pi_0 + 2 \pi_1 + 1 \pi_2 + 0 \pi_3}{3} = 89.3\%$$

©D.L.Bricker, U. of IA, 1999

M/G/1

- *Arrival process is **Memoryless**, i.e., interarrival times have Exponential distribution with mean $1/\lambda$*
- *Single server*
- *Service times are independent, identically-distributed, but not necessarily exponential. Mean service time is $1/\mu$ with variance σ^2*
- *Queue capacity is infinite*

©D.L.Bricker, U. of IA, 1999

M/G/1

Steadystate Characteristics

A steadystate distribution exists if $\rho = \frac{\lambda}{\mu} < 1$
i.e., if service rate exceeds the arrival rate.

$$\pi_0 = 1 - \rho \quad = \textit{probability that server is idle}$$

$$1 - \pi_0 = \rho \quad = \textit{probability that server is busy}$$

i.e., utilization of server

There is no convenient formula for the probability of j customers in system when $j > 0$.

©D.L.Bricker, U. of IA, 1999

M/G/1

Steadystate
Characteristics

$$L_q = \frac{\lambda^2 \sigma^2 + \rho^2}{2(1 - \rho)}$$

*average number of
customers waiting*

After calculating L_q , Little's Formula allows us to compute:

$$W_q = \frac{L_q}{\lambda}, \quad W = W_q + \frac{1}{\mu},$$

$$\& \quad L = \lambda W = L_q + \rho$$

©D.L.Bricker, U. of IA, 1999

For the M/M/1 queue, the standard deviation equals the mean service time, i.e., $\sigma = 1/\mu$ and the coefficient of variation equals 1.0

Using these formulae for the M/G/1 queueing system with $\sigma^2 = 1/\mu^2$ will give results consistent with the formulae for M/M/1.

$$L_q = \frac{\rho^2}{(1 - \rho)}$$

©D.L.Bricker, U. of IA, 1999

$$L_q = \frac{\lambda^2 \sigma^2 + \rho^2}{2(1 - \rho)}$$

Keeping the mean service time fixed, it is clear that the length of the queue is proportional to the variance of the service time.

The more *regular* the service time distribution, i.e., the smaller the coefficient of variation, the *shorter* the queue.

©D.L.Bricker, U. of IA, 1999

$$L_q = \frac{\lambda^2 \sigma^2 + \rho^2}{2(1 - \rho)}$$

The average number in the queue will be *minimized* when the service time is *constant*, i.e., $\sigma^2 = 0$. In this case, the average number in the queue will be exactly *half* of that for the exponential dist'n:

$$L_q = \frac{\rho^2}{2(1 - \rho)}$$

$$\rho = \frac{\lambda}{\mu} < 1$$

©D.L.Bricker, U. of IA, 1999

- The UI Dept. of Public Safety has 5 patrol cars.
- A patrol car breaks down and requires service once every 30 days.
- The dept. has 2 mechanics, each of whom takes an average of 3 days to repair a car.
- Time between breakdowns & repair times have exponential distribution.

What is...

the average # of patrol cars in good condition
the average down time for a car that needs repair

©D.L.Bricker, U. of IA, 1999

A small bank is trying to determine how many tellers to employ.

- Total cost of employing a teller is \$100/day.
 - A teller can serve an average of 60 customers per day (i.e., 8 minutes/customer).
 - An average of 50 customers per day visit the bank.
 - Arrivals form a Poisson process & service times have exponential distribution.
- If delay cost per customer is \$100/day (i.e., about 21¢/minute), how many tellers should be employed?

©D.L.Bricker, U. of IA, 1999

An average of 40 cars/hr. are tempted to use the drive-in window at the Hot Dog King.

- If 5 cars (including the one at the window) are in line, no car will join the line.
- It takes an average of 4 minutes to serve each car (with time having exponential dist'n)

What is...

- ... average # of cars waiting in line?
- ... # cars per hour served?
- ... average waiting time per car?

- An average of 10 persons/hour arrive at the YMCA intending to swim laps.
- Each swimmer intends to swim an average of 30 minutes.
- The Y has 3 lanes open for lap swimming. Each lane can handle 2 swimmers.
- If all 3 lanes are occupied by 2 swimmers, a prospective swimmer becomes disgusted and goes running.

©D.L.Bricker, U. of IA, 1999

What fraction of the time will all 3 lanes be filled?

On the average, how many persons will be swimming?

How many lanes should be allocated to lap swimming to ensure that at most 5% of all prospective swimmers will be turned away?

©D.L.Bricker, U. of IA, 1999

- The manager of an office must decide whether to rent a second copier.
- The cost of a machine is \$40 per 8-hour day, whether used or not.
- An average of 4 workers/hour need to use the copier, and each uses it for an average of 10 minutes.
- Interarrival times & copying times are exponentially distributed.
- Employees are paid \$8/hour, which is assumed to be the cost to the firm of a worker waiting in line for the copier.

How many copiers should be rented?

- An automated car wash will wash a car in 10 minutes.
- Arrivals occur an average of 15 minutes apart (exponentially distributed).
- On the average, how many cars are waiting in line for the car wash?

If the car wash could be speeded up, what wash time would reduce the average wait to 5 minutes?

- Each airline passenger & his/her luggage must be checked to prevent weapons carried onto the plane.
- At the local airport, 10 passengers/minute arrive at the checkpoint.
- A checkpoint can check 12 passengers/minute (with exponential distribution).

*What is the probability that an arriving passenger must wait to be checked?
What is the average time that a passenger spends at the checkpoint?*
