Component Reliability is the probability that the component will *not fail* to perform

- within specified limits
- for a specified period of time
- in a specified environment

Suppose that
 S = strength of component
 s = stress on component
 are both *random variables*

The component fails if $s > S$,
 i.e., stress exceeds strength.

©Dennis Bricker, U. of Iowa, 1998

Component reliability when strength & stress each have Normal distribution.

$$S \text{ (strength)} \sim N(\bar{S}, \sigma_S)$$

$$s \text{ (stress)} \sim N(\bar{s}, \sigma_s)$$

Let $z = S - s$. Then z is $N(\bar{z}, \sigma_z)$,

where $\bar{z} = \bar{S} - \bar{s}$

$$\sigma_z = \sqrt{\sigma_S^2 + \sigma_s^2}$$

$$\text{Then } P\{S > s\} = P\{z > 0\} = P\left\{\frac{z - \bar{z}}{\sigma_z} > \frac{0 - \bar{z}}{\sigma_z}\right\} = 1 - \Phi\left(\frac{-\bar{z}}{\sigma_z}\right)$$

CDF of standard $N(0,1)$ distribution

©Dennis Bricker, U. of Iowa, 1998

Example Suppose that strength (S) and stress (s) are both Normally-distributed random variables:

$$S \sim N(27000, 4000)$$

$$s \sim N(13000, 3000)$$

Then $z = S - s$ is Normally-distributed, with mean $\bar{z} = \bar{S} - \bar{s} = 27000 - 13000 = 14000$ and std.deviation $\sigma_z = \sqrt{\sigma_S^2 + \sigma_s^2}$

$$\left. \begin{array}{l} \text{Probability} \\ \text{of failure} \\ (z \leq 0) \end{array} \right\} \frac{\bar{z}}{\sigma_z} = 2.8$$

$$\Phi(-2.8) = 0.002505$$

Monte Carlo technique to estimate reliability

When strength &/or stress are not Normally-distributed, analytical computation of reliability is generally impossible.

At each trial of the Monte Carlo technique, values of strength and stress are generated randomly with the specified distributions, and are compared to determine whether failure occurs.

$$\text{Reliability is estimated by } 1 - \frac{\# \text{failures}}{\# \text{trials}}$$

©Dennis Bricker, U. of Iowa, 1998

Example Yield values for a certain grade of steel have a sample mean of 25000 psi and standard deviation of 8000 psi.

Maximum loads are found to have a mean of 10000 psi and standard deviation of 7500 psi

Assume that the yield strength has the *Weibull* distribution, and that the load has the *Gumbel* distribution.

Estimate the reliability of the steel, i.e., $P\{\text{Yield value} > \text{maximum load}\}$

©Dennis Bricker, U. of Iowa, 1998

Randomly Generating Random Variables

Both the Weibull and Gumbel distribution functions can be analytically inverted

Weibull $F_W(y) = x \implies F_W^{-1}(x) = y$

Gumbel $F_G(s) = x \implies F_G^{-1}(x) = s$

To generate a random variable by the Inverse Transformation technique, we generate a value for X uniformly distributed in $[0, 1]$ and compute the CDF inverse $F^{-1}(X)$

©Dennis Bricker, U. of Iowa, 1998

Randomly Generating Random Variables

$$F_W(y) = 1 - e^{-(y/u)^k} = \hat{X}$$

uniformly distributed in interval [0,1]

$$e^{-(y/u)^k} = 1 - \hat{X} = X$$

$$-(y/u)^k = \ln X$$

$$\frac{y}{u} = (-\ln X)^{1/k}$$

Weibull $\Rightarrow F_W^{-1}(\hat{X}) = y = u(-\ln x)^{1/k}$

©Dennis Bricker, U. of Iowa, 1998

Computation of Weibull Parameters

Secant Method, solving equation:

$$0.32 = \frac{\sigma_Y}{\mu_Y} = \sqrt{\frac{\Gamma(1+\frac{2}{k})}{\Gamma^2(1+\frac{1}{k})} - 1}$$

k	error
1.000000	0.680000
2.000000	0.202724
2.424751	0.119778
3.038111	0.039357
3.338278	0.010214
3.443479	0.001129
3.456552	0.000036
3.456984	0.000000

$\Rightarrow k = 3.456984$ **shape parameter**

$$u = \frac{\mu_Y}{\Gamma(1+\frac{1}{k})} \Rightarrow u = 27803.718$$
 scale parameter

©Dennis Bricker, U. of Iowa, 1998

Generating Random Yield Strength

$$F_W^{-1}(\hat{X}) = y = u(-\ln x)^{1/k}$$

yield strength $y = 2.7803.718(-\ln x)^{0.289269}$

*Randomly generate X uniformly distributed in [0, 1]
Then compute y, which will have Weibull dist'n!*

©Dennis Bricker, U. of Iowa, 1998

Result of 30 trials

i	Strength	Stress	i	Strength	Stress
1	28713.927	8054.9772	16	21474.919	8350.95

15	24190.804	23212.771	30	20393.457	14387.751

Estimated reliability = 96.666667%

Stress exceeded strength in only 1 of 30 trials!

©Dennis Bricker, U. of Iowa, 1998

Randomly Generating Random Variables

$$F_G(s) = \exp\{-e^{-\alpha(s-u)}\} = X$$

uniformly distributed in interval [0,1]

$$-e^{-\alpha(s-u)} = \ln X$$

$$-\alpha(s-u) = \ln(-\ln X)$$

Gumbel $\Rightarrow F_G^{-1}(X) = s = u - \frac{\ln(-\ln X)}{\alpha}$

©Dennis Bricker, U. of Iowa, 1998

Computation of Gumbel Parameters

$$\sigma_Y \approx \frac{1.282}{\alpha} \Rightarrow \alpha \approx \frac{1.282}{\sigma_Y} = \frac{1.282}{7500}$$

$\alpha = 1.709 \times 10^{-4}$

$$\mu_Y \approx u + \frac{0.577}{\alpha} \Rightarrow u \approx \mu_Y - \frac{0.577}{\alpha}$$

$$\Rightarrow u = 10000 - \frac{0.577}{1.709 \times 10^{-4}}$$

$u = 6624.415$

©Dennis Bricker, U. of Iowa, 1998

Generating Random Load

$$F_G^{-1}(X) = s = u - \frac{\ln(-\ln X)}{\alpha}$$

load (stress) $s = 66.24.415 - \frac{\ln(-\ln x)}{1.709 \times 10^{-4}}$

*Randomly generate X uniformly distributed in [0, 1]
Then compute s, which will have Gumbel dist'n!*

©Dennis Bricker, U. of Iowa, 1998

When the experiment was repeated, but with 300 trials, stress exceeded strength in 26 (i.e., 8.6666%) of the trials, so that the estimated reliability was 91.333%

©Dennis Bricker, U. of Iowa, 1998
