

**Kendall's Notation**

©Dennis Bricker, U. of Iowa, 1997

The "Memoryless" arrival process indicates a Poisson arrival process, in which the interarrival times have an *exponential* distribution.

Likewise, the "Memoryless" service process indicates that the service times have an *exponential* distribution.

**Some Markovian Queues**

- ☞ M/M/1
- ☞ M/M/c (c>1)
- ☞ M/M/1/N
- ☞ M/M/1/N/N

©Dennis Bricker, U. of Iowa, 1997

©Dennis Bricker, U. of Iowa, 1997

**M/M/1**

Interarrival times and service times both have exponential distributions, with parameters  $\lambda$  &  $\mu$ , respectively.

That is, the "customers" arrive at the rate of  $\lambda$  per unit time, and are served at the rate  $\mu$  per unit of time.

It is assumed that the queue has infinite capacity, and that  $\mu > \lambda$  (so that the queue length does not tend to increase indefinitely.)

In this case, it is possible to derive the probability distribution of the number of customers in the queueing system.

©Dennis Bricker, U. of Iowa, 1997

**M/M/1**

**Birth/Death Model**

$$\frac{1}{\pi_0} = 1 + \frac{\lambda}{\mu} + \left(\frac{\lambda}{\mu}\right)^2 + \left(\frac{\lambda}{\mu}\right)^3 + \left(\frac{\lambda}{\mu}\right)^4 + \dots$$

$$= \frac{1}{1 - \frac{\lambda}{\mu}} \quad (\text{Geometric Series})$$

©Dennis Bricker, U. of Iowa, 1997

**M/M/1**

$\pi = (\pi_0, \pi_1, \pi_2, \dots)$  denotes the "steady-state" distribution of the number of customers in this M/M/1 queueing system, i.e., 1+number in queue. Equivalently,  $\pi_i$  is the probability (in steady state) that an arriving customer will find  $i$  customers already in the queueing system.

$$\pi_i = \left(1 - \frac{\lambda}{\mu}\right) \left(\frac{\lambda}{\mu}\right)^i$$

©Dennis Bricker, U. of Iowa, 1997

# PASTA

**P**oisson  
**A**rrivals  
**S**ee  
**T**ime  
**A**verages

PASTA implies that if we observe the system at any random point in time, the probability of the state that we observe will equal the fraction of the time that the system spends in that state!

**M/M/1**

$$\pi_i = \left(1 - \frac{\lambda}{\mu}\right) \left(\frac{\lambda}{\mu}\right)^i$$

$$\pi_0 = 1 - \frac{\lambda}{\mu}$$

Probability that no customers are in the system (server is idle)

Probability that the server is busy

$$1 - \pi_0 = \frac{\lambda}{\mu} \equiv \rho < 1$$

utilization

©Dennis Bricker, U. of Iowa, 1997

**M/M/1**

Average number of "customers" in the system (including any being served)

$$L = \sum_{j=0}^{\infty} j \pi_j = \sum_{j=0}^{\infty} j (1-\rho) \rho^j = (1-\rho) \rho \sum_{j=0}^{\infty} j \rho^{j-1}$$

Next we will derive an expression for this infinite sum!

$$\text{where } \rho = \frac{\lambda}{\mu} < 1$$

**Derivative of a Geometric Series**

This is not a geometric series, because of the appearance of the factor "j", but it is the sum of the derivatives of the terms of a geometric series!

$$\sum_{j=0}^{\infty} j \rho^{j-1} = \frac{d}{d\rho} \sum_{j=0}^{\infty} \rho^j = \frac{d}{d\rho} \left( \frac{1}{1-\rho} \right) = \frac{1}{(1-\rho)^2}$$

Geometric series, with sum  $\left(\frac{1}{1-\rho}\right)$

sum of derivatives equals derivative of the sum!

©Dennis Bricker, U. of Iowa, 1997

**M/M/1**

Average number of "customers" in the system (including any being served)

$$L = \frac{\frac{\lambda}{\mu}}{1 - \frac{\lambda}{\mu}} = \frac{\rho}{1 - \rho}$$

This formula ONLY for M/M/1 queue!

**LITTLE's Queueing Formula**

$$L = \lambda W$$

average number in the queueing system

average arrival rate

average time in system per customer

👉 applies to **any** queueing system having a steady state distribution (**whether Markovian or not!**)

©Dennis Bricker, U. of Iowa, 1997

**LITTLE's Queueing Formula**

$$L = \lambda W$$

Intuitive argument:

Suppose that you join a queue and spend **W** minutes before you have been served and leave. During those **W** minutes, customers have been arriving and joining the queue behind you at the average rate of **λ** per minute. Thus, when you are ready to leave, you should expect to see **λW** customers remaining in the system behind you.

you enter queue

time 0

entered queue behind you

time W

**M/M/1**

For the M/M/1 queueing system, Little's formula implies that

$$W = \frac{L}{\lambda} = \frac{\rho}{\lambda(1-\rho)} \quad \text{where } \rho = \lambda/\mu$$

$$\Rightarrow W = \frac{1}{\mu - \lambda}$$

©Dennis Bricker, U. of Iowa, 1997

Denote

$L_q$  = average number of customers in the queue (not including those being served)

$W_q$  = average time spent per customer in the queue (not including service time)

Then for any queueing system having a steady state distribution,

$$W_q = W - \frac{1}{\mu} \quad \text{average rate of service}$$

$$L_q = \lambda W_q \quad \text{Little's Formula}$$

©Dennis Bricker, U. of Iowa, 1997

©Dennis Bricker, U. of Iowa, 1997

Thus, given any one of the quantities

$L$ ,  $W$ ,  $L_q$ , and  $W_q$

we can compute the others.

(Generally,  $L$  is the easiest to compute first!)

**M/M/1**

For the M/M/1 queueing system, then

$$W_q = W - \frac{1}{\mu} \Rightarrow W_q = \frac{\lambda}{\mu(\mu - \lambda)}$$

$$L_q = \lambda W_q \Rightarrow L_q = \frac{\lambda^2}{\mu(\mu - \lambda)}$$

©Dennis Bricker, U. of Iowa, 1997

©Dennis Bricker, U. of Iowa, 1997

**Example**

An average of 24 trucks per 8-hour day arrive to be unloaded &/or loaded, which requires an average of 15 minutes.

The loading dock can handle only a single truck at a time.

Assume that the arrival process is Poisson, and that the service times have exponential distribution.

This loading dock is modeled as an M/M/1 queue.

**M/M/1**

$\lambda$  = arrival rate = 3/hour

$\mu$  = service rate = 4/hour

Utilization of the server  $\rho = \frac{\lambda}{\mu} = 0.75$

Average number of trucks in system  $L = \frac{\rho}{1 - \rho} = \frac{0.75}{1 - 0.75} = 3$

Average time in system per truck  $W = \frac{L}{\lambda} = \frac{3}{3/\text{hr}} = 1 \text{ hr.}$

Steady-State Behavior

©Dennis Bricker, U. of Iowa, 1997

**M/M/1**

$\lambda$  = arrival rate = 3/hour

$\mu$  = service rate = 4/hour

Average time in the queue  $W_q = W - \frac{1}{\mu} = 1 \text{ hr.} - \frac{1}{4/\text{hr}} = 0.75 \text{ hr.}$

Average length of the queue  $L_q = \lambda W_q = (3/\text{hr})(0.75 \text{ hr}) = 2.25$

**Example**

The arrival process at a certain work center is Poisson, with rate 3/hour. The service time has exponential distribution, with mean 0.3 hr. Each job waiting for processing requires 1 m<sup>2</sup> of floor space. How much in-process storage space should be allocated to accomodate all waiting jobs

- ... 90% of the time?
- ... 95% of the time?
- ... 99% of the time?

, U. of Iowa, 1997

©Dennis Bricker, U. of Iowa, 1997

If n square meters of floor space are allocated, this will be sufficient a fraction of time equal to

$$P(\text{number in system} \leq n+1) = \sum_{j=0}^{n+1} \pi_j$$

$$\pi_j = \rho^j (1 - \rho)$$

$$\Rightarrow \sum_{j=0}^{n+1} \pi_j = \sum_{j=0}^{n+1} \rho^j (1 - \rho)$$

$$= (1 - \rho) \sum_{j=0}^{n+1} \rho^j = (1 - \rho) \left[ \frac{1 - \rho^{n+2}}{1 - \rho} \right]$$

$$= 1 - \rho^{n+2}$$

sum of finite geometric series

©Dennis Bricker, U. of Iowa, 1997

Solving for n:  $1 - \rho^{n+2} \geq \alpha$

$$\Rightarrow \rho^{n+2} \leq 1 - \alpha$$

$$(n+2) \log \rho \leq \log (1 - \alpha)$$

$$n+2 \geq \frac{\log (1 - \alpha)}{\log \rho}$$

$$n \geq \left\lceil \frac{\log (1 - \alpha)}{\log \rho} - 2 \right\rceil \quad \& \text{ integer!}$$

©Dennis Bricker, U. of Iowa, 1997

$$n \geq \frac{\log(1 - \alpha)}{\log \rho} - 2$$
