- ☒ Problem Formulation

- Lagrangian Relaxation of

- ☒ Machine Capacity Constraints

- ☒ Job Assignment Constraints

- ☒ References

In the classical **Assignment Problem**, we must find the least-cost, one-to-one assignment of **n** jobs to **n** machines:

Minimize $\sum_{i=1}^m \sum_{j=1}^n C_{ij} X_{ij}$
subject to

$$\sum_{j=1}^n X_{ij} = 1 \text{ for all } i \quad \leftarrow \begin{array}{l} \text{Each machine is} \\ \text{assigned only one} \\ \text{job!} \end{array}$$
$$\sum_{i=1}^m X_{ij} = 1 \text{ for all } j \quad \leftarrow \begin{array}{l} \text{Each job is assigned} \\ \text{to one machine} \end{array}$$
$$X_{ij} \in \{0,1\} \text{ for all } i \& j$$

Suppose that job # j requires a_{ij} units of processing time on machine # i , which has a total of b_i time units available.

Then the constraint $\sum_{j=1}^n X_{ij} = 1 \text{ for all } i$

which says that exactly one job is assigned to machine # i

is replaced by $\sum_{j=1}^n a_{ij} X_{ij} \leq b_i \text{ for all } i$

which says that the total time required to process the jobs assigned to machine # i cannot exceed b_i , the time available.

Thus, the Generalized Assignment Problem is

Minimize $\sum_{i=1}^m \sum_{j=1}^n C_{ij} X_{ij}$

subject to

$$\sum_{j=1}^n a_{ij} X_{ij} \leq b_i \quad \text{for all } i$$

*no more than
the available
capacity of
machine i is
used*

$$\sum_{i=1}^m X_{ij} = 1 \quad \text{for all } j$$

*each job must
be assigned to
exactly one
machine*

$$X_{ij} \in \{0,1\} \quad \text{for all } i \& j$$

Example:

4 jobs must be processed, each on one
of 3 machines which are available

Data:

job:	1	2	3	4	hrs available	
machine:	1	6	4	9	7	15
	2	3	2	6	4	8
	3	5	4	7	6	12
<i>Time Req'd (hrs)</i>						

Data:

The cost of processing a job varies, according to the machine to which it is assigned:

		job: 1	2	3	4	
machine:	1	18	15	20	16	Cost
	2	10	9	15	10	
	3	12	12	18	13	

Minimize $18X_{11} + 15X_{12} + 20X_{13} + 16X_{14} + 10X_{21} + 9X_{22} + 15X_{23} + 10X_{24}$
 $+ 12X_{31} + 12X_{32} + 18X_{33} + 13X_{34}$

subject to

$$6X_{11} + 4X_{12} + 9X_{13} + 7X_{14} \leq 15$$

$$3X_{21} + 2X_{22} + 6X_{23} + 4X_{24} \leq 8$$

$$5X_{31} + 4X_{32} + 7X_{33} + 6X_{34} \leq 12$$

$$X_{11} + X_{21} + X_{31} = 1$$

$$X_{12} + X_{22} + X_{32} = 1$$

$$X_{13} + X_{23} + X_{33} = 1$$

$$X_{14} + X_{24} + X_{34} = 1$$

$X_{ij} \in \{0,1\}$ for all i & j

Lagrangian Relaxation:

Lagrangian relaxation is based upon the fact that, if we relax (ignore) one set of constraints of the GAP, the problem that remains is much easier to solve.

The assignment problem is an LP with the property that every basic solution is integer... so that AP is very easy to solve!

In the case of the Generalized Assignment Problem, not all basic solutions are integer-valued, so that solving the problem with the integer restrictions ignored, i.e., as an LP, generally yields a non-integer solution (i.e., jobs may be split between two or more machines.)

If we relax the machine availability constraints, however, the problem that remains is rather trivial to solve:

$$\text{Minimize } \sum_{i=1}^m \sum_{j=1}^n C_{ij} X_{ij}$$

subject to

$$\sum_{i=1}^m X_{ij} = 1 \quad \text{for all } j$$

*each job must
be assigned to
exactly one
machine*

$$X_{ij} \in \{0,1\} \quad \text{for all } i \& j$$

In Lagrangian Relaxation, we assign a "Lagrange Multiplier" to every relaxed constraint, and shift the constraint to the objective:

Minimize $\sum_{i=1}^m \sum_{j=1}^n C_{ij} X_{ij} + \sum_{i=1}^m v_i \left(\sum_{j=1}^n a_{ij} X_{ij} - b_i \right)$

subject to

$$\sum_{i=1}^m X_{ij} = 1 \quad \text{for all } j \quad \leftarrow \begin{array}{l} \text{each job must} \\ \text{be assigned to} \\ \text{exactly one} \\ \text{machine} \end{array}$$
$$X_{ij} \in \{0,1\} \quad \text{for all } i \text{ & } j$$

This simplifies to

$$\left(- \sum_{i=1}^m v_i b_i \right) + \sum_{j=1}^n \left\{ \text{minimum} \sum_{i=1}^m (C_{ij} + a_{ij} v_i) X_{ij} \right\}$$

subject to

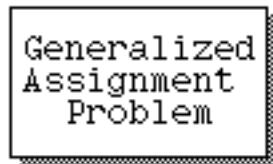

$$\sum_{i=1}^m X_{ij} = 1 \quad \text{for all } j \quad \leftarrow \begin{array}{l} \text{each job must} \\ \text{be assigned to} \\ \text{exactly one} \\ \text{machine} \end{array}$$

$$X_{ij} \in \{0,1\} \quad \text{for all } i \& j$$

That is, we must assign every job to *exactly one* machine, but we can ignore the machine capacity constraints.

The solution is obviously to assign each job to the machine which can process it most cheaply.

Consider our example GAP:

***** Example GAP *****

Machine <hr/>	<u>Costs</u>			
	<u>1</u>	<u>2</u>	<u>3</u>	<u>4</u>
1	18	15	20	16
2	10	9	15	10
3	12	12	18	13

Machine	Resources Used				Available
	1	2	3	4	
1	6	4	9	7	15
2	3	2	6	4	8
3	5	4	7	6	12

Lambda = 0.75 \leftarrow target value & stepsize parameter
Target Z* = 50 for subgradient optimization of dual

Iteration # 1

Multiplier vector U = 0 0 0

Objective function of relaxation:

Resources used are: 16 2 5, (Available: 15 8 12)

Subgradient of Dual Objective is 1 -6 -7

Stepsize is 0.07763

Integrality Property

A Lagrangian relaxation exhibits the "Integrality Property" if, when the integer restriction is relaxed, the resulting problem will still possess an integer solution.

The optimal value of the associated Lagrangian dual problem, if the Lagrangian relaxation has the integrality property, is identical to that of the LP relaxation.

$$\left(- \sum_{i=1}^m v_i b_i \right) + \sum_{j=1}^n \left\{ \begin{array}{l} \text{minimum} \sum_{i=1}^m (C_{ij} + a_{ij} v_i) X_{ij} \\ \text{subject to} \\ \sum_{i=1}^m X_{ij} = 1 \quad \text{for all } j \\ \hline X_{ij} \in \{0,1\} \quad \text{for all } i \& j \\ \hline 0 \leq X_{ij} \leq 1 \quad \text{for all } i \& j \end{array} \right.$$

This Lagrangian relaxation does exhibit the "Integrality Property".

Consider again the original GAP:

$$\begin{aligned}
 & \text{Minimize} && \sum_{i=1}^m \sum_{j=1}^n C_{ij} X_{ij} \\
 & \text{subject to} && \sum_{j=1}^n a_{ij} X_{ij} \leq b_i \quad \text{for all } i \leftarrow \\
 & && \text{no more than} \\
 & && \text{the available} \\
 & && \text{capacity of} \\
 & && \text{machine } i \text{ is} \\
 & && \text{used} \\
 & && \sum_{i=1}^m X_{ij} = 1 \quad \text{for all } j \leftarrow \\
 & && \text{each job must} \\
 & && \text{be assigned to} \\
 & && \text{exactly one} \\
 & && \text{machine} \\
 & && X_{ij} \in \{0,1\} \quad \text{for all } i \& j
 \end{aligned}$$

Before, we relaxed the machine resource constraints.
Suppose that we relax instead the Multiple-Choice
(GUB) constraints:

$$\sum_{i=1}^m X_{ij} = 1 \text{ for all } j$$

This gives us the Lagrangian Relaxation:

Minimize $\sum_{i=1}^m \sum_{j=1}^n C_{ij} X_{ij} + \sum_{j=1}^n u_j \left(\sum_{i=1}^m X_{ij} - 1 \right)$

subject to $\sum_{j=1}^n a_{ij} X_{ij} \leq b_i \text{ for all } i$ *no more than the available capacity of machine i is used*

$X_{ij} \in \{0,1\}$ for all i & j

The Lagrangian Relaxation

$$\begin{aligned}
 & \text{Minimize} && \sum_{i=1}^m \sum_{j=1}^n C_{ij} X_{ij} + \sum_{j=1}^n u_j \left(\sum_{i=1}^m X_{ij} - 1 \right) \\
 & \text{subject to} && \sum_{j=1}^n a_{ij} X_{ij} \leq b_i \quad \text{for all } i \\
 & && X_{ij} \in \{0,1\} \quad \text{for all } i \& j
 \end{aligned}$$

is rewritten

$$\begin{aligned}
 & \left(- \sum_{j=1}^n u_j \right) + \text{Minimize} && \sum_{i=1}^m \sum_{j=1}^n (C_{ij} + u_j) X_{ij} \\
 & \text{subject to} && \sum_{j=1}^n a_{ij} X_{ij} \leq b_i \quad \text{for all } i \\
 & && X_{ij} \in \{0,1\} \quad \text{for all } i \& j
 \end{aligned}$$

This separates into one knapsack problem for each machine:

$$\text{Minimize} \sum_{j=1}^n (C_{ij} + u_j) X_{ij}$$

$$\text{subject to} \quad \sum_{j=1}^n a_{ij} X_{ij} \leq b_i$$

$$X_{ij} \in \{0,1\} \text{ for all } j$$

From the sum of the optimal values of the knapsacks,
we then subtract

$$\sum_{j=1}^n u_j$$

to get a *lower bound* on the optimum of the GAP.

Consider our example GAP again:

Iteration # 1

Current multipliers:

i:	1	2	3	4
w[i]:	0	0	0	0

Solving knapsack problems:

Machine #1
NO items
Machine #2
NO items
Machine #3
NO items

since we have
relaxed the require-
ment that each job
be assigned to a
machine!

*** Dual value is 0 ***
