Batch Processing Problem Markov Decision Model

This Hypercard stack was prepared by: Dennis L. Bricker, Dept. of Industrial Engineering, University of Iowa, Iowa City, Iowa 52242

e-mail: dbricker@icaen.uiowa.edu

Each minute, either zero, one, or two customers arrive at a facility which has a capacity (batch size) of 5.

i=#waiting	0	1	2	3	4
P{0 arrivals}	0.04	0.25	0.44	0.61	0.76
P{1 arrival}	0.6	0.5	0.4	0.3	0.2
P{2 arrivals}	0.36	0.25	0.16	0.09	0.04

(Probability of arrival diminishes as the queue lengthens... probability of 2 arrivals is square of probability of one.)

There is a "holding cost" per customer of 10¢ per minute, and a processing cost of 40¢ per batch (independent of batch size).

What is the optimal queue length for batch processing?

(The smaller the batches, the more the processing cost, while the larger the batches, the more the holding cost.)

Markov Decision Model

States

i	name
1	0 waiting
2	1 waiting
3	2 waiting
4	3 waiting
5	4 waiting
6	1 ≥5 waiting

Actions

	k
ite	1 2
ï	2

state defined as number in the queue at the beginning of the stage (minute) before any arrivals

Cost Matrix

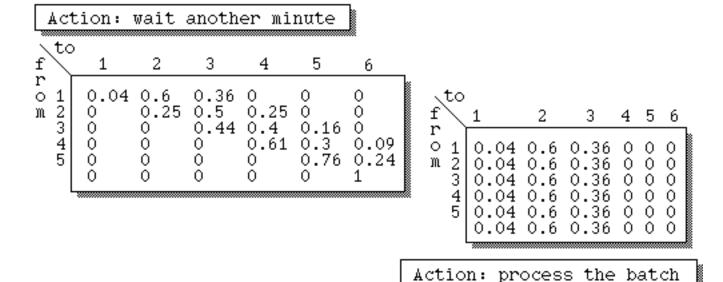

name	1	2	3	4	5	6
wait another minute	0	0.1	0.2	0.3	0.4	999
process batch	0.4	0.5	0.6	0.7	0.8	0.9

A value of 999 above signals an infeasible action in a state.

(Rows ~ actions, Columns ~ states)

includes holding cost for customers in queue at beginning of stage

Transition Probabilities
