## **Median Problem**

minimizing the sum of weighted  
shortest path lengths

## **Center Problem**

minimizing the maximum of (possibly)  
weighted shortest path lengths

## The p-Median Problem

Given a network with nodes  $j=1,2,\dots,n$   
 where  $w_j$  = "weight" of node  $j$   
 (e.g., volume of shipments)

Let  $d(X,j)$  = distance from node  $j$  to  
 the nearest point in the set  $X$

Find  $X = \{x_1, x_2, \dots, x_p\}$  which

minimizes 
$$\tau(X) = \sum_{j=1}^n w_j d(X,j)$$

*The points in  $X$  are  
 called p-medians.*

©Dennis Bricker, U. of Iowa, 1997

## Hakimi's Theorem

At least one set of p-medians  
 exist solely on the nodes of  
 the network.

*That is, we need search only among the nodes  
 for the p-medians!*

*Where should a single facility be located to serve the eight cities?*

*Objective:  
Minimize the sum of the distances to the cities weighted by their demands*

 **Minimum**

*The optimal location for a single facility to serve the 8 cities is at city C*

*What if two facilities were to be used?*

©Dennis Bricker, U. of Iowa, 1997

Consider all pairs of potential facility sites:

Examples: *select minimum shipping cost in each column*

A	0	4	6	6	6	0	32	6
B	12	0	4	9	4	0	28	5

$$47 = \sum_j \text{minimum}_{i=A,B} \{W_j d_{ij}\}$$

D	6	3	2	0	4	0	24	4
E	18	4	6	12	0	0	32	6

$$39 = \sum_j \text{minimum}_{i=D,E} \{W_j d_{ij}\}$$

A	0	4	6	6	6	0	32	6
G	24	7	10	18	8	0	0	3

$$25 = \sum_j \text{minimum}_{i=A,G} \{W_j d_{ij}\}$$

There are  $\binom{8}{2} = 28$  such combinations to evaluate!

©Dennis Bricker, U. of Iowa, 1997

How might one find the 3-median set?

Requires considering  $\binom{8}{3} = 56$  combinations!

A	0	4	6	6	6	0	32	6
B	12	0	4	9	4	0	28	5
C	9	2	0	3	3	0	20	3

$$29 = \sum_j \text{minimum}_{i=A,B,C} \{W_j d_{ij}\}$$

A	0	4	6	6	6	0	32	6
B	12	0	4	9	4	0	28	5
D	6	3	2	0	4	0	24	4

$$34 = \sum_j \text{minimum}_{i=A,B,D} \{W_j d_{ij}\}$$

etc.

## Math Programming Model of the p-Median Problem

### *Variables*

$X_{ij}$  = fraction of demand of customer  $j$  supplied  
by facility at location  $i$

$Y_i = \begin{cases} 1 & \text{if a facility is located at site } i \\ 0 & \text{otherwise} \end{cases}$

©Dennis Bricker, U. of Iowa, 1997

## Math Programming Model of the p-Median Problem

$$\text{Min } \sum_{i=1}^m \sum_{j=1}^n W_j D_{ij} X_{ij}$$

subject to

$$\sum_{i=1}^m X_{ij} = 1 \quad \forall j=1, \dots, n$$

$$X_{ij} \leq Y_i \quad \forall i=1, \dots, m; j=1, \dots, n$$

$$\sum_{i=1}^m Y_i = p$$

$$X_{ij} \geq 0 \quad \forall i=1, \dots, m; j=1, \dots, n$$

$$Y_i \in \{0, 1\} \quad \forall i=1, \dots, m$$

## Heuristic Algorithm for the p-Median Problem

### 1. Initialization:

Let  $k=1$ . Find the 1-median (the set  $S=X_1$ )

### 2. Facility Addition:

Evaluate the  $(n-k)$  combinations of  $S$  with a node  $r$  not in  $S$ , i.e.,

$$\sum_j \text{minimum} \{W_j d_{ij}\} \quad \forall r \notin S$$

Add to  $S$  the node yielding the lowest objective function and set  $k=k+1$ .

### 3. Facility Substitution:

Evaluate each of the  $k \times (n-k)$  sets obtained by substituting a node not in  $S$  for a node in  $S$ , i.e.

$$\sum_j \text{minimum}_{i \in S \cup \{r\} \setminus \{s\}} \{W_j d_{ij}\} \quad \forall r \notin S \ \& \ s \in S$$

Replace  $S$  by the best set evaluated.

- 4. If  $S$  contains  $p$  nodes, i.e.,  $k=p$ , STOP.  
Otherwise, return to step 2.

## 1-Median of a Tree

For any set  $C$  of vertices, define  $W(C) = \sum_{i \in C} w_i$

### Theorem

Let  $[a,b]$  be any edge of a tree, and

let  $A$  = set of vertices reachable from  $a$  without passing through  $b$

$B$  = set of vertices reachable from  $b$  without passing through  $a$ .

Then  $W(A) \geq W(B)$  implies  $\tau(a) \leq \tau(b)$

©Dennis Bricker, U. of Iowa, 1997

$W(A) \geq W(B)$  implies  $\tau(a) \leq \tau(b)$

©Dennis Bricker, U. of Iowa, 1997

To find the 1-median of a tree:

0. Let  $W = \sum_{i \in N} w_i$ . Select any vertex  $j$ .
1. If  $w_j \geq \frac{1}{2} W$ , then stop;  $j$  is a 1-median.
2. If  $j$  has degree 1, let  $k$  be its neighbor, i.e.,  $[k, j]$  will be an edge.

Replace  $w_k$  with  $w_k + w_j$ , and delete vertex  $j$  from the tree.

Else find an elementary chain from vertex  $j$  to a vertex  $k$  with degree 1 (preferably using previously unused edges.)

Let  $j=k$  and return to step 1.

©Dennis Bricker, U. of Iowa, 1997

**Example**

Find the 1-median of the tree:

©Dennis Bricker, U. of Iowa, 1997

Let's choose to begin with vertex #7.

Total "demand"  $W = \sum_{i \in N} w_i$  is 30.

©Dennis Bricker, U. of Iowa, 1997

$w_7 < \frac{W}{2} = 15$ . Select neighbor (vertex #6), and replace  $w_6$  with  $w_6 + w_7 = 3$ . Delete vertex #7.

$w_6 < \frac{W}{2} = 15$ . Find a path 6→8 to a vertex (#8) with degree 1:

$w_8 < \frac{W}{2} = 15$ . Select neighbor (vertex #6),  
 update  $w_6$ , and delete vertex #8:

$w_6 < \frac{W}{2} = 15$ . Select neighbor (vertex #5),  
 update  $w_5$ , and delete vertex #6:

$w_5 < \frac{W}{2} = 15$ . Select chain  $5 \rightarrow 9 \rightarrow 10 \rightarrow 12$  to vertex #12, which has degree 1.

$w_{12} < \frac{W}{2} = 15$ . Select neighbor (vertex #10), update  $w_{10}$ , and delete vertex #12

... after several more iterations, the tree is as shown, where vertex #9 is being considered.

$w_9 < \frac{W}{2} = 15$ , so we select its neighbor (vertex #5), update  $w_5$ , and delete vertex #9.

$w_5 > \frac{16}{2} = 8$ , so we stop; Vertex #5 is the 1-median.

$W(A) \geq W(B)$  implies  $\tau(a) \leq \tau(b)$

Edge (5,9):  $W(9) = 14 < 22 = W(5)$  implies  $\tau(9) > \tau(5)$

$W(A) \geq W(B)$  implies  $\tau(a) \leq \tau(b)$

Edge [5,4]:  $W(5) = 22 > 8 = W(4)$  implies  $\tau(4) > \tau(5)$
