The property of "CONVEXITY" of sets and of functions is central to most approaches to nonlinear programming.

**Convex Set**

**Convex Function**

*The more "unified" approach first defines convexity of sets, and bases the definition of convex function upon convexity of sets.*

**Convex Set**

A set  $S$  is CONVEX if for every pair of elements  $x$  and  $y$  in  $S$ , the line segment joining  $x$  and  $y$  also lies in  $S$ .

This means that, if we are solving the problem

Minimize  $f(x)$   
 subject to  $x \in S$

and  $S$  is convex, that there is a linear path such that we can follow this path directly from the starting point  $x \in S$  to the optimal solution  $y \in S$  without leaving the set  $S$ .

*Unfortunately, we are seldom able to determine this line!*

The **line segment** between  $x$  and  $y$  is given by

$$\lambda y + (1-\lambda)x = x + \lambda(y-x) \quad \text{for } \lambda \in [0,1]$$

where

- $\lambda=0 \Rightarrow \lambda y + (1-\lambda)x = x$
- $\lambda=1 \Rightarrow \lambda y + (1-\lambda)x = y$
- $\lambda=1/2 \Rightarrow \lambda y + (1-\lambda)x = 1/2(x+y)$  (midpt of segment), etc.

**Example**

Let  $x=(0,1)$  and  $y=(4, -1)$  be points in the plane.

| $\lambda$ | $\lambda y + (1-\lambda)x$ |
|-----------|----------------------------|
| 0         | (0, 1)                     |
| 0.25      | (1, 0.5)                   |
| 0.50      | (2, 0)                     |
| 0.75      | (3, -0.5)                  |
| 1         | (4, -1)                    |

**line segment**

**Convex Combination**

If  $x^{(1)}, x^{(2)}, \dots, x^{(k)}$  are vectors in  $R^n$ , and  $\lambda_1, \lambda_2, \dots, \lambda_k$  are nonnegative numbers whose

sum is 1, i.e.,  $\sum_{i=1}^k \lambda_i = 1$

then  $\lambda_1 x^{(1)} + \lambda_2 x^{(2)} + \dots + \lambda_k x^{(k)}$  is a convex combination (weighted average) of

$$x^{(1)}, x^{(2)}, \dots, x^{(k)}$$

*In particular, a point on a line segment is a convex combination of the endpoints of the segment!*

The **CONVEX HULL** of a set of points is the set of all convex combinations of those points.

*Convex hull of  $\{x^{(1)}, x^{(2)}, x^{(3)}, x^{(4)}, x^{(5)}\}$*

**Theorem** If  $x^{(1)}, x^{(2)}, \dots, x^{(k)} \in S$  where  $S$  is a convex set, then every convex combination of the points  $x^{(1)}, x^{(2)}, \dots, x^{(k)}$  is an element of  $S$ .

*That is, if  $S$  is convex then  $S$  equals its convex hull.*

**Convex Function** A function  $f(x)$  is *convex* if:

$$f(\lambda x^{(1)} + (1-\lambda)x^{(2)}) \leq \lambda f(x^{(1)}) + (1-\lambda)f(x^{(2)}) \quad \forall \lambda \in [0,1]$$

*For example,  $f$  evaluated at the midpoint of two points is less than the average of the function values at the two points.*

Definition #1

**Convex Function** A function  $f(x)$  is *convex* if:

$$f(\lambda x^{(1)} + (1-\lambda)x^{(2)}) \leq \lambda f(x^{(1)}) + (1-\lambda)f(x^{(2)}) \quad \forall \lambda \in [0,1]$$

Definition #2

**Convex Function** A differentiable function  $f(x)$  is *convex* if:

the tangent line (hyperplane) to the graph lies on or below the graph:

Property of convex function

**Convex Function** A differentiable function  $f(x)$  is *convex* if:

$$f(x^{(1)}) + f'(x^{(1)})(x^{(2)} - x^{(1)}) \leq f(x^{(2)})$$

Property of convex function

**Epigraph** The epigraph of a function is the set  $\text{epi}(f) = \{(y,x) \mid y \geq f(x)\}$

**Convex Function** A function  $f(x)$  is *convex* if the set  $\text{epi}(f)$  is convex

*relationship between the concepts of convexity of a set and of a function!*

For any real value  $c$ , the **Level Set** of the function  $f$  is the set

$$L_c^f = \{x \mid f(x) \leq c\}$$

If  $f$  is a convex function, then  $L_c^f$  is convex.

However, the convexity of the level sets does NOT imply convexity of the function.

If all the level sets of a function are convex, then the function is *quasi*convex.

**Examples**

**Concave Function**

A function  $f$  is *concave* if

- its negative,  $(-f)$ , is convex
- a chord between 2 points on the graph lies on or below the graph
- a tangent line (hyperplane) to the graph lies on or above the graph
- the hypergraph  $\{(y,x) \mid y \leq f(x)\}$  is convex

**Examples**

A linear function is *both* convex and concave!

A function may be neither convex nor concave:
