

(s,S) inventory replenishment system

Example: (s,S) Inventory Control System with Periodic Review

Suppose that the inventory of a certain item is counted at the end of each business day, after a random demand has occurred.

If the number of units is $\leq s=2$, the *reorder point*, enough is ordered to bring the inventory level up to $S=6$. (Assume that the replenishment is instantaneous.)

The daily *demand* has probability distribution:

| Demand d | 0 | 1 | 2 | 3 | 4 | 5 | ≥ 6 |
|------------|---------|--------|-------|-------|-------|--------|----------|
| $P\{D=d\}$ | 0.04979 | 0.1494 | 0.224 | 0.224 | 0.168 | 0.1008 | 0.05041 |

(which is *Poisson* with expected value 3).

Define

- ♦ the *state* of the system to be the inventory level, i.e.,
 $I = \{0, 1, 2, \dots, 6\}$ before any replenishment, and
- ♦ the *stages* to be the days.

Transition probabilities are:

$$p_{ij} = \begin{cases} P\{D=i-j\} & \text{if } i>s \text{ and } i \geq j \\ P\{D=S-j\} & \text{if } i \leq s \\ 0 & \text{otherwise} \end{cases}$$

Examples of system characteristics that may be of interest:

- ♦ if the system begins in state $S=6$, what is the probability of the first stockout occurring 3 days hence?

① *Answer:* $f_{S,0}^{(3)}$

- ♦ if the system begins in state $S=6$, what is the average length of time until a stockout (zero inventory) occurs?

① *Answer:* $m_{S,0}$

DTMC@ s,S inventory system

page 3

©D.Bricker, U. of Iowa, 2001

- ♦ if the system begins in state S , what is the expected number of stockouts during the next n days?

① *Answer:* $\sum_{k \leq n} p_{S,j}^{(n)}$

- ♦ over a sufficiently long period of time, what is the fraction of the days that the end-of-day inventory level is i ?

① *Answer:* π_i

Transition Probabilities

| from \ to | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|-----------|---------|--------|--------|---------|---------|---------|---------|
| 0 | 0.08392 | 0.1008 | 0.168 | 0.224 | 0.224 | 0.1494 | 0.04979 |
| 1 | 0.08392 | 0.1008 | 0.168 | 0.224 | 0.224 | 0.1494 | 0.04979 |
| 2 | 0.08392 | 0.1008 | 0.168 | 0.224 | 0.224 | 0.1494 | 0.04979 |
| 3 | 0.5768 | 0.224 | 0.1494 | 0.04979 | 0 | 0 | 0 |
| 4 | 0.3528 | 0.224 | 0.224 | 0.1494 | 0.04979 | 0 | 0 |
| 5 | 0.1847 | 0.168 | 0.224 | 0.224 | 0.1494 | 0.04979 | 0 |
| 6 | 0.08392 | 0.1008 | 0.168 | 0.224 | 0.224 | 0.1494 | 0.04979 |

Note that because the state is the inventory level before replenishments, the transition probabilities out of states 0, 1, and 2=s are identical to those for state S=6.

Thus, $p_{64} = P\{\text{Demand} = 6 - 4 = 2\} = 0.224$, and
 $p_{30} = P\{\text{Demand} \geq 3\} = 0.5768$

Two simulations of 20 stages of the system, beginning with full inventory:

In both of these realizations of the process, four stockouts have occurred during the first 20 days of operation.

The expected number of visits to state j during the first n stages, if the system begins in state i, may be found by summing the first n powers of P. In this particular case,

$$\sum_{k=1}^{20} P^k =$$

| from \ to | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|-----------|---------|---------|---------|---------|---------|---------|----------|
| 0 | 4.35285 | 2.92231 | 3.55777 | 3.65758 | 3.06261 | 1.85714 | 0.589734 |
| 1 | 4.35285 | 2.92231 | 3.55777 | 3.65758 | 3.06261 | 1.85714 | 0.589734 |
| 2 | 4.35285 | 2.92231 | 3.55777 | 3.65758 | 3.06261 | 1.85714 | 0.589734 |
| 3 | 4.72536 | 3.00256 | 3.52746 | 3.51926 | 2.90429 | 1.7616 | 0.559473 |
| 4 | 4.54813 | 3.01517 | 3.60129 | 3.6023 | 2.9318 | 1.74659 | 0.554716 |
| 5 | 4.43127 | 2.97713 | 3.60575 | 3.66134 | 3.00358 | 1.77409 | 0.546833 |
| 6 | 4.35285 | 2.92231 | 3.55777 | 3.65758 | 3.06261 | 1.85714 | 0.589734 |

Thus, we would expect approximately $\sum_{k=1}^{20} p_{6,0}^{(k)} = 4.35$ stockouts during the first twenty days of operation, if the inventory is initially full.

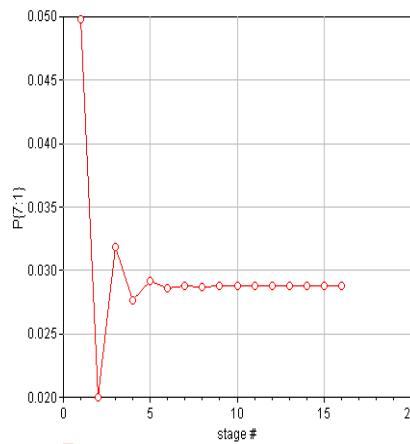

P^2 , the second power of the transition probability matrix, is

| from \ to | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|-----------|--------|--------|--------|--------|--------|---------|---------|
| 0 | 0.2696 | 0.1661 | 0.1848 | 0.1683 | 0.1237 | 0.06756 | 0.02004 |
| 1 | 0.2696 | 0.1661 | 0.1848 | 0.1683 | 0.1237 | 0.06756 | 0.02004 |
| 2 | 0.2696 | 0.1661 | 0.1848 | 0.1683 | 0.1237 | 0.06756 | 0.02004 |
| 3 | 0.1085 | 0.107 | 0.1671 | 0.2154 | 0.2129 | 0.1419 | 0.04731 |
| 4 | 0.1709 | 0.1254 | 0.168 | 0.1943 | 0.1819 | 0.1196 | 0.03987 |
| 5 | 0.2395 | 0.1502 | 0.175 | 0.1738 | 0.1441 | 0.08863 | 0.02872 |
| 6 | 0.2696 | 0.1661 | 0.1848 | 0.1683 | 0.1237 | 0.06756 | 0.02004 |

and the third power is

| from \ to | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|-----------|--------|--------|--------|--------|--------|---------|---------|
| 0 | 0.2069 | 0.1413 | 0.1756 | 0.1855 | 0.1597 | 0.09903 | 0.03189 |
| 1 | 0.2069 | 0.1413 | 0.1756 | 0.1855 | 0.1597 | 0.09903 | 0.03189 |
| 2 | 0.2069 | 0.1413 | 0.1756 | 0.1855 | 0.1597 | 0.09903 | 0.03189 |
| 3 | 0.2616 | 0.1631 | 0.1839 | 0.1706 | 0.1281 | 0.07126 | 0.0214 |
| 4 | 0.2406 | 0.1552 | 0.1813 | 0.1766 | 0.1399 | 0.08126 | 0.0251 |
| 5 | 0.2173 | 0.146 | 0.1778 | 0.183 | 0.1534 | 0.09305 | 0.02954 |
| 6 | 0.2069 | 0.1413 | 0.1756 | 0.1855 | 0.1597 | 0.09903 | 0.03189 |

Consider the behavior of $P_{6,0}^{(n)}$ as n increases:

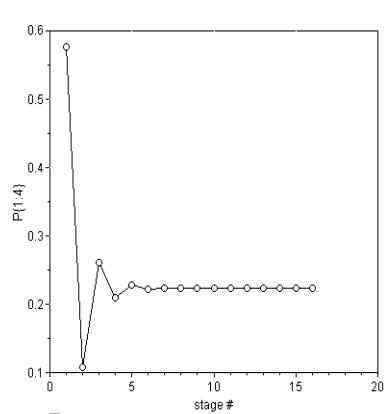

| n | $P_{6,0}^{(n)}$ |
|-----|-----------------|
| 1 | 0.0839179 |
| 2 | 0.269638 |
| 3 | 0.206912 |
| 4 | 0.228275 |
| 5 | 0.220989 |
| 6 | 0.223475 |
| 7 | 0.222627 |
| 8 | 0.222916 |
| 9 | 0.222818 |
| 10 | 0.222851 |
| 11 | 0.22284 |
| 12 | 0.222844 |
| 13 | 0.222842 |
| 14 | 0.222843 |
| 15 | 0.222843 |
| 16 | 0.222843 |

The limiting distribution of the state of the system (independent of the initial state) is

| State i | Steadystate Probability π_i |
|---------------------------------|---|
| 0 | 0.222843 |
| 1 | 0.14779 |
| 2 | 0.178159 |
| 3 | 0.181227 |
| 4 | 0.150444 |
| 5 | 0.0907828 |
| 6 | 0.0287543 |

This implies that 22.2843% of the days a stockout occurs, 14.779% of the days the ending inventory is 1, etc.

Compare to the behavior of $P_{4,0}^{(n)}$ as n increases:

| n | $P_{4,0}^{(n)}$ |
|-----|-----------------|
| 1 | 0.57681 |
| 2 | 0.108458 |
| 3 | 0.261614 |
| 4 | 0.209636 |
| 5 | 0.227347 |
| 6 | 0.221306 |
| 7 | 0.223367 |
| 8 | 0.222664 |
| 9 | 0.222904 |
| 10 | 0.222822 |
| 11 | 0.22285 |
| 12 | 0.22284 |
| 13 | 0.222844 |
| 14 | 0.222842 |
| 15 | 0.222843 |
| 16 | 0.222843 |

Recursive Computation of First-Passage Probabilities

$$f_{ij}^{(n)} = p_{ij}^{(n)} - \sum_{k < n} p_{jj}^{(n-k)} f_{ij}^{(k)} \text{ where } f_{ij}^{(l)} \equiv p_{ij}$$

$$f_{6,0}^{(1)} = p_{6,0} = 0.08392$$

$$f_{6,0}^{(2)} = p_{6,0}^{(2)} - [p_{0,0}^{(1)} f_{6,0}^{(1)}] = 0.2696 - 0.08392 \times 0.08392 = 0.26256$$

$$f_{6,0}^{(3)} = p_{6,0}^{(3)} - [p_{0,0}^{(1)} f_{6,0}^{(2)} + p_{0,0}^{(2)} f_{6,0}^{(1)}] = 0.2069 - [0.08392 \times 0.26256 + 0.2696 \times 0.08392] = 0.1622$$

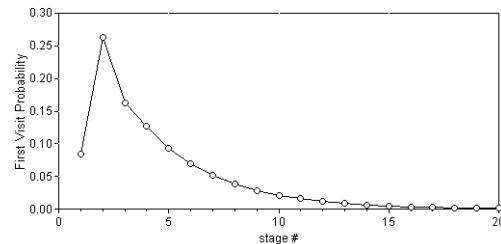

etc.

Thus, if the inventory is full on Monday morning (or equivalently, Sunday evening),

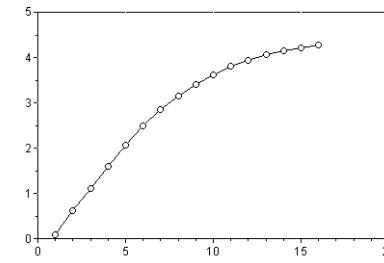

the probability that the *first stockout* occurs Wednesday evening (n=3) is 16.22%.

The probability distribution $f_{6,0}^{(n)}$ of the first-passage times are

| n | $f_{6,0}^{(n)}$ |
|----|-----------------|
| 1 | 0.0839179 |
| 2 | 0.262596 |
| 3 | 0.162248 |
| 4 | 0.12649 |
| 5 | 0.0931353 |
| 6 | 0.0694925 |
| 7 | 0.0516882 |
| 8 | 0.0384743 |
| 9 | 0.0286333 |
| 10 | 0.0213104 |
| 11 | 0.0158602 |
| 12 | 0.0118039 |
| 13 | 0.00878497 |
| 14 | 0.00653818 |
| 15 | 0.00486601 |
| 16 | 0.00362151 |

The partial sums in the last column are successive approximations of the **mean first passage time** $m_{6,0}$, but convergence is somewhat slow:

Expectation of First Passage Time

| n | $f_{6,0}^{(n)}$ | $n \times f_{6,0}^{(n)}$ | $\sum_{k \leq n} k \times f_{6,0}^{(k)}$ |
|----|-----------------|--------------------------|--|
| 1 | 0.0839179 | 0.0839179 | 0.0839179 |
| 2 | 0.262596 | 0.525192 | 0.60911 |
| 3 | 0.162248 | 0.486745 | 1.09586 |
| 4 | 0.12649 | 0.50596 | 1.60182 |
| 5 | 0.0931353 | 0.465677 | 2.06749 |
| 6 | 0.0694925 | 0.416955 | 2.48445 |
| 7 | 0.0516882 | 0.361818 | 2.84627 |
| 8 | 0.0384743 | 0.307794 | 3.15406 |
| 9 | 0.0286333 | 0.2577 | 3.41176 |
| 10 | 0.0213104 | 0.213104 | 3.62486 |
| 11 | 0.0158602 | 0.174462 | 3.79933 |
| 12 | 0.0118039 | 0.141646 | 3.94097 |
| 13 | 0.00878497 | 0.114205 | 4.05518 |
| 14 | 0.00653818 | 0.0915345 | 4.14671 |
| 15 | 0.00486601 | 0.0729902 | 4.2197 |
| 16 | 0.00362151 | 0.0579441 | 4.27765 |

Generally, it is more computationally efficient to compute the mean first passage times by solving a (7×7) system of linear equations for $m_{i,0}$, $i = 0, 1, \dots, 6$:

$$\text{Fix } j=0: \begin{cases} m_{0,0} = 1 + p_{0,1}m_{1,0} + p_{0,2}m_{2,0} + p_{0,3}m_{3,0} + \dots + p_{0,6}m_{6,0} \\ m_{1,0} = 1 + p_{1,1}m_{1,0} + p_{1,2}m_{2,0} + p_{1,3}m_{3,1} + \dots + p_{1,6}m_{6,1} \\ \text{etc.} \\ m_{6,0} = 1 + p_{6,1}m_{1,0} + p_{6,2}m_{2,0} + p_{6,3}m_{3,1} + \dots + p_{6,6}m_{6,1} \end{cases}$$

That is, we solve the 7×7 linear system for $m_{0,0}, m_{1,0}, \dots, m_{6,0}$:

$$\begin{array}{ccccccc|c} 1 & -0.100819 & -0.168031 & -0.224042 & -0.224042 & -0.149361 & -0.0497871 & 1 \\ 0 & 0.899181 & -0.168031 & -0.224042 & -0.224042 & -0.149361 & -0.0497871 & 1 \\ 0 & -0.100819 & 0.831969 & -0.224042 & -0.224042 & -0.149361 & -0.0497871 & 1 \\ 0 & -0.224042 & -0.149361 & 0.950213 & 0 & 0 & 0 & 1 \\ 0 & -0.224042 & -0.224042 & -0.149361 & 0.950213 & 0 & 0 & 1 \\ 0 & -0.168031 & -0.224042 & -0.224042 & -0.149361 & 0.950213 & 0 & 1 \\ 0 & -0.100819 & -0.168031 & -0.224042 & -0.224042 & -0.149361 & 0.950213 & 1 \end{array}$$

The complete *mean first passage* matrix is found by solving 7 such linear systems (one per column):

| from \ to | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|-----------|---------|---------|---------|---------|---------|---------|---------|
| 0 | 4.48747 | 6.76636 | 5.61296 | 4.75467 | 5.77744 | 10.1005 | 34.7774 |
| 1 | 4.48747 | 6.76636 | 5.61296 | 4.75467 | 5.77744 | 10.1005 | 34.7774 |
| 2 | 4.48747 | 6.76636 | 5.61296 | 4.75467 | 5.77744 | 10.1005 | 34.7774 |
| 3 | 2.81583 | 6.22338 | 5.78307 | 5.51794 | 6.82984 | 11.1529 | 35.8298 |
| 4 | 3.61112 | 6.13803 | 5.36867 | 5.05969 | 6.64699 | 11.3183 | 35.9952 |
| 5 | 4.13554 | 6.39543 | 5.34364 | 4.73395 | 6.16983 | 11.0153 | 36.2693 |
| 6 | 4.48747 | 6.76636 | 5.61296 | 4.75467 | 5.77744 | 10.1005 | 34.7774 |

Thus, starting with a full inventory (state 6), the expected number of days until a stockout occurs (state 0) is 4.48747.

The **mean recurrence times** m_{ii} on the diagonal are the reciprocals

of the steady-state probabilities, i.e., $m_{ii} = 1/\pi_i$.

For example, one should expect a stockout once every

$$m_{00} = 1/\pi_0 = \frac{1}{0.222843} = 4.48747 \text{ (days)}$$

and to find the inventory full ($S=6$) at the end of the day once every

$$m_{6,6} = 1/\pi_6 = \frac{1}{0.0287543} = 34.7774 \text{ (days)}$$
