

# Birth-Death Processes

## Steadystate Probabilities

To calculate steady-state probability distribution, we use "Balance" equations:

$$\text{Rate at which system enters state } \#i = \text{Rate at which system leaves state } \#i$$

## Steady-State Distribution of a Birth-Death Process

Balance Equations:

State 1: Rate leaving state #1 = Rate entering state #1

$$(\lambda_1 + \mu_1) \pi_1 = \lambda_0 \pi_0 + \mu_2 \pi_2$$

$$\Rightarrow \pi_2 = \frac{(\lambda_1 + \mu_1) \pi_1 - \lambda_0 \pi_0}{\mu_2} = \frac{(\lambda_1 + \mu_1) \frac{\lambda_0 \pi_0}{\mu_1} - \lambda_0 \pi_0}{\mu_2}$$

$$\Rightarrow \pi_2 = \frac{\lambda_1 \lambda_0 \pi_0}{\mu_2 \mu_1}$$

$$\pi_i = \left( \frac{\lambda_{i-1}}{\mu_i} \right) \cdots \left( \frac{\lambda_1}{\mu_2} \right) \left( \frac{\lambda_0}{\mu_1} \right) \pi_0$$

$$= \rho_{i-1} \cdots \rho_1 \rho_0 \pi_0 \quad \text{where } \rho_i = \frac{\lambda_i}{\mu_{i+1}}$$

ratio of transition rates between adjacent states

## Birth-Death Process

A birth-death process is a continuous-time Markov chain which models the size of a population; the population increases by 1 ("birth") or decreases by 1 ("death").

## Steady-State Distribution of a Birth-Death Process

Balance Equations:

State 0:  $\lambda_0 \pi_0 = \mu_1 \pi_1 \Rightarrow \pi_1 = \frac{\lambda_0}{\mu_1} \pi_0$

Rate leaving state #0 = Rate entering state #0

In general,

$$(\lambda_{i-1} + \mu_{i-1}) \pi_{i-1} = \lambda_{i-2} \pi_{i-2} + \mu_i \pi_i$$

$$\Rightarrow \pi_i = \frac{\lambda_{i-1} \cdots \lambda_1 \lambda_0}{\mu_i \cdots \mu_2 \mu_1} \pi_0 \quad i=1,2,3, \dots$$

Substituting these expressions for  $\pi_i$  into

$$\sum_{i=0}^{\infty} \pi_i = 1 \quad \text{yields:}$$

$$\pi_0 + \sum_{i=1}^{\infty} \frac{\lambda_{i-1} \cdots \lambda_1 \lambda_0}{\mu_i \cdots \mu_2 \mu_1} \pi_0 = 1$$

$$\Rightarrow \pi_0 \left[ 1 + \sum_{i=1}^{\infty} \frac{\lambda_{i-1} \cdots \lambda_1 \lambda_0}{\mu_i \cdots \mu_2 \mu_1} \right] = 1$$

$$\Rightarrow \frac{1}{\pi_0} = \left[ 1 + \sum_{i=1}^{\infty} \frac{\lambda_{i-1} \cdots \lambda_1 \lambda_0}{\mu_i \cdots \mu_2 \mu_1} \right]$$

©Dennis Bricker, U. of Iowa, 1997

Once  $\pi_0$  is evaluated by computing the reciprocal of this infinite sum,  $\pi_i$  is easily computed for each  $i=1, 2, 3, \dots$

$$\frac{1}{\pi_0} = \left[ 1 + \sum_{i=1}^{\infty} \frac{\lambda_{i-1} \cdots \lambda_1 \lambda_0}{\mu_i \cdots \mu_2 \mu_1} \right]$$

$$\pi_i = \frac{\lambda_{i-1} \cdots \lambda_1 \lambda_0}{\mu_i \cdots \mu_2 \mu_1} \pi_0 \quad i=1, 2, 3, \dots$$

**Example**

An airlines reservation system has 2 computers, one on-line and one standby. The operating computer fails after an exponentially-distributed duration having mean  $t_f$  and is then replaced by the standby computer.

There is one repair facility, and repair times are exponentially-distributed with mean  $t_r$ .  
*What fraction of the time will the system fail, i.e., both computers having failed?*

©Dennis Bricker, U. of Iowa, 1997

$$\frac{1}{\pi_0} = 1 + \frac{1/t_r}{1/t_f} + \left( \frac{1/t_r}{1/t_f} \right)^2$$

$$\frac{1}{\pi_0} = 1 + \frac{t_f}{t_r} + \left( \frac{t_f}{t_r} \right)^2$$

$$\pi_0 = \frac{t_r^2}{t_r^2 + t_r t_f + t_f^2}$$

*probability that both computers have failed*

©Dennis Bricker, U. of Iowa, 1997

A gasoline station has only one pump. Cars arrive at the rate of 20/hour.

However, if the pump is already in use, these potential customers may "balk", i.e., drive on to another gasoline station.

If there are  $n$  cars already at the station, the probability that an arriving car will balk is  $n/4$ , for  $n=1, 2, 3, 4$ , and 1 for  $n > 4$ . Time required to service a car is exponentially distributed, with mean = 3 minutes.

What is the expected waiting time of customers?

©Dennis Bricker, U. of Iowa, 1997

**Examples**

Backup Computer System

Gasoline Station

Ticket Sales by Phone

©Dennis Bricker, U. of Iowa, 1997

Let  $X(t)$  = number of computers in operating condition at time  $t$ . Then  $X(t)$  is a birth-death process.

*Note that the birth rate in state 2 is zero!*

©Dennis Bricker, U. of Iowa, 1997

Suppose that  $\frac{t_f}{t_r} = 10$ , i.e., the average repair time is 10% of the average time between failures:

$$\frac{1}{\pi_0} = 1 + 10 + 100 = 111$$

$$\pi_0 = \frac{1}{111} = 0.009009$$

Then both computers will be simultaneously out of service 0.9% of the time.

"Birth/death" model:

$$\begin{aligned} \frac{1}{\pi_0} &= 1 + \frac{20}{20} + \frac{20 \times 15}{20 \times 20} + \frac{20 \times 15 \times 10}{20 \times 20 \times 20} + \frac{20 \times 15 \times 10 \times 5}{20 \times 20 \times 20 \times 20} \\ &= 1 + 1 + 0.75 + 0.375 + 0.09375 = 3.21875 \\ \pi_0 &= 0.3106796 \end{aligned}$$

**Steady State Distribution**

$$\begin{aligned} \pi_0 &= 0.3106796, \\ \pi_1 &= \pi_0 = 0.3106796, \\ \pi_2 &= 0.75\pi_0 = 0.2330097, \\ \pi_3 &= 0.375\pi_0 = 0.1165048, \\ \pi_4 &= 0.09375\pi_0 = 0.0291262 \end{aligned}$$

**Average Number in System**

$$\begin{aligned} L &= \sum_{i=0}^4 i \pi_i \\ &= 0.3106796 + 2(0.2330097) \\ &\quad + 3(0.1165048) + 4(0.0291262) \\ &= 1.2427183 \end{aligned}$$

**Average Arrival Rate**

$$\begin{aligned} \bar{\lambda} &= \sum_{i=0}^4 \lambda_i \pi_i \\ &= (0.3106796) \times 20/\text{hr} + (0.3106796) \times 15/\text{hr} \\ &\quad + (0.2330097) \times 10/\text{hr} + (0.1165048) \times 5/\text{hr} \\ &\quad + (0.0291262) \times 0/\text{hr} \\ &= 13.786407/\text{hr} \end{aligned}$$

**Average Time in System**

$$\begin{aligned} W &= L/\bar{\lambda} = \frac{1.2427183}{13.786407/\text{hr}} \\ &= 0.0901408 \text{ hr.} = 5.40844504 \text{ minutes} \end{aligned}$$

Hancher Auditorium has 2 ticket sellers who answer phone calls & take incoming ticket reservations, using a single phone number.

In addition, 2 callers can be put "on hold" until one of the two ticket sellers is available to take the call.

If all 4 phone lines are busy, a caller will get a busy signal, and waits until later before trying again.

Calls arrive at an average rate of 2/minute, and ticket reservations service time averages 20 sec. and is exponentially distributed.

What is...

- the fraction of the time that each ticket seller is idle?
- the fraction of customers who get a busy signal?
- the average waiting time ("on hold")?

**BIRTH-DEATH MODEL**
