Suppose that we wish to minimize a nonlinear function subject to nonlinear equality &/or inequality constraints:

Minimize $f(x)$
 subject to
 $h_i(x) = 0, \quad i=1,2,..m_1$
 $g_i(x) \leq 0, \quad i=1,2, ...m_2$
 $x \in R^n$

SUMT:
Sequential Unconstrained Minimization Technique

The approach to be presented here will replace the constrained problem with a sequence of unconstrained nonlinear optimization problems:

$$\text{Minimize}_{x \in R^n} \Phi(x) = f(x) + \sum_{i=1}^{m_1} \psi[h_i(x)] + \sum_{i=1}^{m_2} \phi[g_i(x)]$$

There are two types of such approaches:

- **barrier functions** (inequality case only)

For x interior to the feasible region, a large penalty is incurred as the point nears the boundary

Example: $\phi(x,r) = f(x) + \frac{r}{g(x)}$
 $\phi(x,r) \rightarrow \infty$ as $g(x) \rightarrow 0$

- **penalty functions**

A large penalty is incurred for infeasible values of x .

Example: $\phi(x,r) = f(x) + r [g^+(x)]^2$
 where $z^+ = \max(0, z)$
 $\phi(x,r)$ is large for $g(x) > 0$ (infeasible)

Penalty Functions

Barrier Functions

Penalty Functions

Minimize $f(x)$
 subject to
 $h_i(x) = 0, \quad i=1,2,..m_1$
 $g_i(x) \leq 0, \quad i=1,2, ...m_2$
 $x \in X \subseteq R^n$

$$\Phi(x) = f(x) + \sum_{i=1}^{m_1} \psi[h_i(x)] + \sum_{i=1}^{m_2} \phi[g_i(x)]$$

where ψ and ϕ are continuous functions satisfying

$$\begin{cases} \psi(y)=0 & \text{if } y=0 \\ \psi(y)>0 & \text{if } y \neq 0 \end{cases} \quad \Leftrightarrow \quad \begin{cases} \phi(y)=0 & \text{if } y \leq 0 \\ \phi(y)>0 & \text{if } y > 0 \end{cases}$$

Typical Penalty Functions

$$\psi[h_i(x)] = r |h_i(x)|^p$$

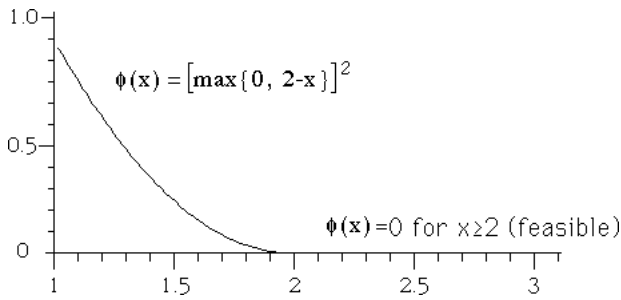

$$\phi[g_i(x)] = r [g_i(x)^+]^p = r [\max\{0, g_i(x)\}]^p$$

for some positive integer p and parameter r .

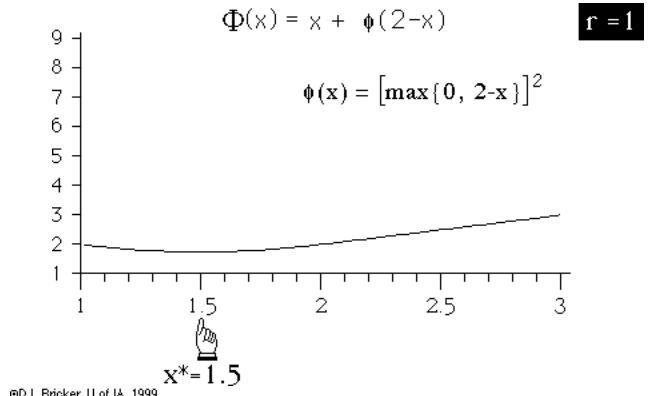

Example

Minimize x
 subject to $-x + 2 \leq 0$ *i.e.,*
 $x \geq 2$

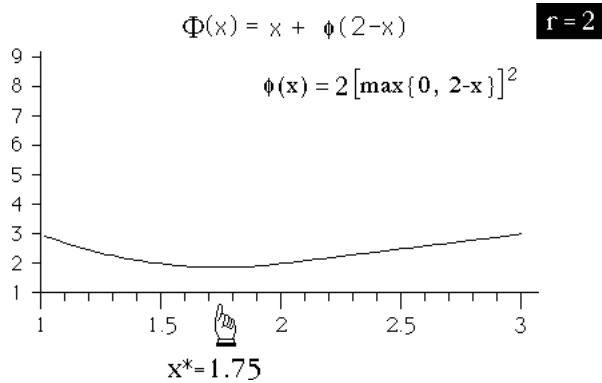

Let $\phi(y) = r [y^+]^2$

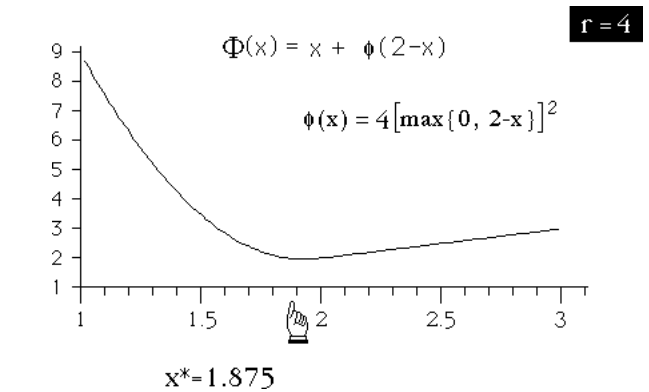

©D.L.Bricker, U.of IA, 1999

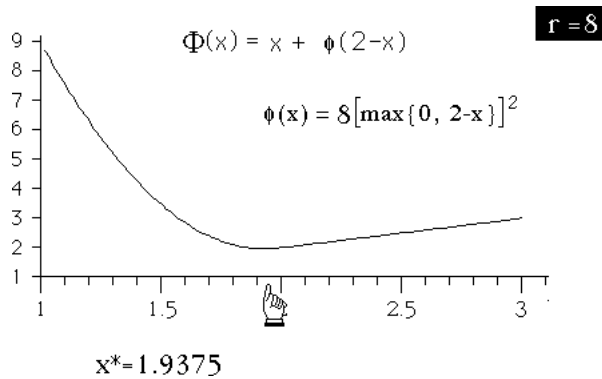

©D.L.Bricker, U.of IA, 1999

©D.L.Bricker, U.of IA, 1999

$$\Phi(x) = x + \phi(2-x) = \begin{cases} x & \text{if } x \geq 2 \quad \text{i.e., } 2-x \leq 0 \\ x + rx^2 - 4rx + 4r & \text{if } x \leq 2 \end{cases}$$

The minimum of $\Phi(x)$ occurs at $x^*(r) = 2 - \frac{1}{2r}$ which approaches the solution of the original problem ($x^*=2$) as $r \rightarrow \infty$

©D.L.Bricker, U.of IA, 1999

Example

Minimize $x_1^2 + x_2^2$
 subject to
 $x_1 + x_2 - 1 = 0$

optimum: $\frac{1}{2}$ at $(\frac{1}{2}, \frac{1}{2})$

Penalty function approach:

Minimize $\Phi(x) = x_1^2 + x_2^2 + r(x_1 + x_2 - 1)^2$
 subject to $x \in \mathbb{R}^2$

$\Phi(x)$ is convex for any $r \geq 0$

The necessary & sufficient conditions for a minimum of $\Phi(x)$ are

$$\nabla \Phi(x) = \begin{bmatrix} x_1 + r(x_1 + x_2 - 1) \\ x_2 + r(x_1 + x_2 - 1) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\Rightarrow x_1^*(r) = x_2^*(r) = \frac{r}{2r+1}$$

As $r \rightarrow \infty$, $x^*(r) \rightarrow (\frac{1}{2}, \frac{1}{2}) = x^*$

Penalty Function Algorithm

parameters:
 tolerance $\epsilon > 0$
 penalty reduction factor $\beta > 1$

- Step 0: Choose an initial point x^0 & penalty factor r^0
 Let $k=0$
- Step 1: Starting with x^k , minimize $\Phi(x)$ s.t. $x \in R^n$
 Denote the optimal solution by x^{k+1}
- Step 2: If $\Phi(x^{k+1}) - f(x^{k+1}) < \epsilon$, stop; otherwise,
 let $r^{k+1} = \beta r^k$, $k = k+1$, and go to step 1.

Theorem

Suppose that

- \Rightarrow the problem has a feasible solution
- $\Rightarrow f, h_i (1 \leq i \leq m_1)$, and $g_j (1 \leq j \leq m_2)$ are continuous functions
- \Rightarrow for each r , there exists a solution $x^*(r)$ to the problem
 Minimize $\Phi(x)$ s.t. $x \in X$, and $\{x^*(r)\}$ is contained in a compact subset of X .

Then

$$\Rightarrow \lim_{r \rightarrow \infty} \Phi(x^*(r)) = \sup_{r \geq 0} \Phi(x^*(r)) = \inf \{f(x) : g(x) \leq 0, h(x) = 0, x \in X\}$$

\Rightarrow the limit of any convergent subsequence of $\{x^*(r)\}$ is an optimal solution

Barrier Functions

Minimize $f(x)$
 subject to
 $g_i(x) \leq 0, \quad i=1,2, \dots, m$
 $x \in R^n$

Typical barrier functions

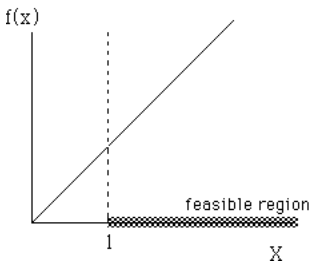

- $\phi_1(g(x)) = -1/g(x)$
- $\phi_2(g(x)) = -\frac{1}{[g(x)]^2}$
- $\phi_3(g(x)) = -\ln |g(x)|$

$$\Theta(x) = f(x) + \sum_{i=1}^m \phi[g_i(x)]$$

where ϕ is a function of one variable, continuous over domain $\{y: y < 0\}$, and satisfies

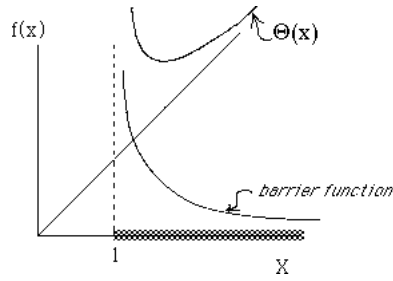

$$\phi(y) \geq 0 \text{ if } y < 0 \text{ and } \lim_{y \rightarrow 0^-} \phi(y) = \infty$$

Example

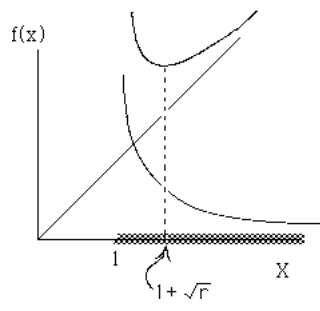

Minimize x
 subject to $-x + 1 \leq 0$

i.e., $x \geq 1$

$\Theta(x) = x + \phi(-x+1)$
 where $\phi(y) = -r/y$
 $\Theta(x) = x - \frac{r}{1-x}$

$$\Theta(x) = x - \frac{r}{1-x}$$

$$\frac{d}{dx} \Theta(x) = 1 + \frac{r}{(1-x)^2} = 0$$

$$\Rightarrow x = 1 + \sqrt{r}$$

As $r \rightarrow 0, x^* \rightarrow 1$
